FOREWORD

The Unified Facilities Criteria (UFC) system is prescribed by MIL-STD 3007 and provides planning, design, construction, sustainment, restoration, and modernization criteria, and applies to the Military Departments, the Defense Agencies, and the DoD Field Activities in accordance with [USD \(AT&L\) Memorandum](#) dated 29 May 2002. UFC will be used for all DoD projects and work for other customers where appropriate. All construction outside of the United States, its territories, and possessions is also governed by Status of Forces Agreements (SOFA), Host Nation Funded Construction Agreements (HNFA), and in some instances, Bilateral Infrastructure Agreements (BIA). Therefore, the acquisition team must ensure compliance with the most stringent of the UFC, the SOFA, the HNFA, and the BIA, as applicable.

UFC are living documents and will be periodically reviewed, updated, and made available to users as part of the Military Department's responsibility for providing technical criteria for military construction. Headquarters, U.S. Army Corps of Engineers (HQUSACE), Naval Facilities Engineering Systems Command (NAVFAC), and Air Force Civil Engineer Center (AFCEC) are responsible for administration of the UFC system. Technical content of UFC is the responsibility of the cognizant DoD working group. Defense Agencies should contact the respective DoD Working Group for document interpretation and improvements. Recommended changes with supporting rationale may be sent to the respective DoD working group by submitting a Criteria Change Request (CCR) via the Internet site listed below.

UFC are effective upon issuance and are distributed only in electronic media from the following source:

- Whole Building Design Guide website <https://www.wbdg.org/dod>.

Refer to UFC 1-200-01, *DoD Building Code*, for implementation of new issuances on projects.

**UNIFIED FACILITIES CRITERIA (UFC)
REVISION SUMMARY SHEET**

Document: UFC 3-301-01, Change 1, Dated October 2, 2023

Superseding: UFC 3-301-01, Dated April 11, 2023

\\

Description of changes:

This update to UFC 3-301-01 incorporates a change to Tsunami design provisions wherein “other utilities”, which would generally refer to elements of secondary or tertiary importance, may be designed for a reduced risk category where approved by the AHJ. Additionally, an existing prohibition against the use of fabric hangar doors in windborne debris regions has been changed to include fabric covered buildings in general in windborne debris regions.

Reason for changes:

Regarding tsunami design change: In some cases it may be infeasible to harden all elements of a utility system against tsunami effects, particularly less critical distributions systems. Accordingly, it was decided that the Authority Having Jurisdiction (AHJ) can approve the reduction of tsunami risk category for “other utilities”, which can have the effect of reducing or eliminating tsunami design requirements for secondary and/or tertiary systems.

Regarding fabric covered buildings in windborne debris regions: It became apparent that there was an omission in DoD structural criteria, wherein an existing prohibition against the use of fabric covered hangar doors existed, while there was no such prohibition against using fabric covered buildings in general, which are vulnerable to the same failure mode. Moreover, this omission would result in a prohibition against the use of a fabric door on a fabric covered building, which would prove illogical. Awareness of this omission occurred as a result of a recent emphasis on the utilization of fabric covered buildings across the Department of Defense. Fabric, unlike other construction materials is uniquely vulnerable to tearing and tear propagation due to windborne debris. Past experience with Hurricane Michael at Tyndall Air Force Base has demonstrated this vulnerability.

Impact: There are both costs and benefits to these changes

Tsunami design changes: This change will result in substantial cost savings to the Department of Defense over time, where the department is impacted by tsunami.

Fabric covered structures: A direct increase in cost will be negligible for this change, as the life cycle cost for a fabric covered building, compared to a metal clad building, will not vary significantly for windborne debris regions. Ultimately however, it is expected that this prohibition will result in considerable savings to DoD, by reducing facility loss and facility content loss due to damage caused by major hurricanes and typhoons.

/1/

Document: UFC 3-301-01, Change 2, Dated September 4, 2024

Superseding: UFC 3-301-01, Change 1, Dated October 2, 2023

\2

Description of changes (seismic coefficients):

Seismic design values for OCONUS installations have been updated (effective Sept 4, 2024). This will affect existing OCONUS RFP's and designs according to UFC 1-200-01 (Chapter 1-3.1).

Reason for changes:

Seismic acceleration coefficients (earthquake loading) for OCONUS installations have not been fully updated since the 1990's. At that time, they were prepared based on less reliable information. In 2010, the Global Earthquake Model (GEM), a non-profit foundation, began a multi-year effort to construct a global earthquake hazard model using high quality site hazard data available from governments, academia, and industry resources. This Model is continuously refined and improved. In 2021, the Department of Defense (DoD), in partnership with the Department of State (DoS), contracted with GEM to develop new seismic design values for all OCONUS DoD installations and DoS facilities using the GEM model. Results from this effort have recently become available and have been incorporated into DoD design criteria (effective Sept 4, 2024).

Impact:

There may be a significant cost increase for some locations. Because prior values were based on less reliable information, this update has resulted in numerous changes. In most cases changes are mild to moderate. However, in a few locations, values have increased markedly. For this reason, this change has the potential to result in a significant cost increase for some locations.

/2/

\2

Description of changes (fall protection):

Two separate sections referencing fall protection were consolidated and simplified.

Reason for changes:

Fall protection requirements noted within the UFC were confusing as written, redundant to the IBC and ASCE 7 and, in some cases, were not relevant to the building structure.

Impact:

There is no significant impact associated with this change.

/2/

\2

Description of changes (Roof Diaphragms Resisting Wind Loads in High-wind Regions):

An exception was added to this provision to prevent it from being applied to new buildings.

Reason for changes:

As written, the provision could be incorrectly applied to new buildings.

Impact:

There is no significant impact associated with this change.

/2/

Document: UFC 3-301-01, Change 3, Dated February 3, 2025

Superseding: UFC 3-301-01, Change 2, Dated September 4, 2024

\3\

Description of changes:

-Adoption of the 2024 I-codes

-Adoption of ASCE 7-22, Minimum Design Loads and Associated Criteria for Buildings and Other Structures

-Frost depth, for the purpose of foundation design, is now to be determined by project geotechnical engineer

Reason for changes:

Maintain concurrence with model building codes and alignment with DoD building code (1-200-01).

Impact:

Typical of the code update cycle.

/3/

Document: UFC 3-301-01, Change 4, Dated June 3, 2025

Superseding: UFC 3-301-01, Change 3, Dated February 3, 2025

\4\

Description of changes:

Includes sundry changes and clarifications but also a significant change to the risk category table (Table 2-2).

Reason for change:

- There is a conflict originating in the IBC, where public utilities are designated as both risk category III and IV. This has been corrected by deletion of the risk category III option for public utilities. It is not intended that this change affect current projects in any stage of design.
- The application of Risk Category V in the context of missile defense has gradually expanded beyond its original intent, which was to protect nationally critical

defensive assets. The current revision realigns the category's use with its initial purpose—focusing on missile defense and other highly critical assets whose loss could result in catastrophic national consequences, rather than merely regional or local impact.

Impact: This change will result in substantial cost savings

CHAPTER 1 INTRODUCTION

1-1 BACKGROUND.

UFC 1-200-01 implements and supplements 2024 IBC as the building code for DoD. Chapter 2 of this UFC further modifies the IBC for structural-specific design requirements and is organized by the chapter of the IBC that each section modifies. Apply any section in the 2024 IBC, that is not specifically referenced, as it is written in the 2024 IBC. Chapter 3 of this UFC further modifies ASCE 7-22 for structural-specific design requirements and is organized by the chapter of ASCE 7 that each section modifies. Apply any section in ASCE 7-22, that is referenced by the 2024 IBC but is not modified in Chapter 3 of this UFC, as it is written in ASCE 7-22.

The 2024 IBC and ASCE 7-22 section modifications are one of four actions, according to the following legend:

[Addition] – Add new section, including new section number, not shown in 2024 IBC or ASCE 7-22.

[Deletion] – Delete referenced 2024 IBC or ASCE 7-22 section or noted portion of a section.

[Replacement] – Delete referenced 2024 IBC or ASCE 7-22 section or noted portion and replace it with the narrative shown.

[Supplement] – Add narrative shown as a supplement to the narrative shown in the referenced section of 2024 IBC or ASCE 7-22.

1-2 REISSUE AND CANCELS.

This edition of UFC 3-301-01 cancels UFC 3-301-01 dated 1 October 2019.

1-3 PURPOSE AND SCOPE.

This Unified Facilities Criteria (UFC) provides requirements for structures designed and constructed for the Department of Defense (DoD). These technical requirements are based on the 2024 *International Building Code* (2024 IBC), as modified by UFC 1-200-01, *DoD Building Code*, and the structural standard referenced by the 2024 IBC: ASCE/SEI 7-22 *Minimum Design Loads and Associated Criteria for Buildings and Other Structures* (hereinafter referred to simply as ASCE 7-22). The criteria further provides limited technical guidance for seismic evaluation and strengthening of existing buildings, and references ICSSC RP 10, *Standards of Seismic Safety for Existing Federally Owned and Leased Buildings* (RP 10) as well as ASCE/SEI 41-17, *Seismic Evaluation and Retrofit of Existing Buildings* (hereinafter referred to simply as ASCE 41-17). Additionally, for nonseismic retrofit of existing buildings, the criteria references the 2024 edition of the *International Existing Building Code* (2024 IEBC). This information is for use by structural engineers to develop design calculations, specifications, plans, and

design-build Requests for Proposal (RFPs), and it is meant to serve as the minimum design requirement for DoD buildings.

1-4 APPLICABILITY.

This UFC follows the same applicability as UFC 1-200-01, paragraph 1-3, with no exceptions.

1-5 CONFLICTS AND MODIFICATIONS.

The 2024 IBC provisions are directed toward public health, safety, and general welfare, presenting minimum standards that must be met by the private sector construction industry. The use of industry standards for DoD projects promotes communication in the marketplace, improves competition, and results in cost savings. However, the military sometimes requires higher standards to achieve unique building performance, or to construct types of facilities that are not used in the private sector. In addition, the construction of military facilities outside the United States can introduce requirements that are not addressed in national model building codes. Modifications to the 2024 IBC and ASCE 7-22 provisions contained herein are intended to fulfill those unique military requirements. Where conflicts between the 2024 IBC or ASCE 7-22 and this UFC arise, this UFC prevails.

In addition, for construction outside the United States, conflicts between host nation building codes and the UFC may arise. In those instances, the more stringent design provisions prevail.

1-6 OVERVIEW OF THIS UFC.

Brief descriptions of the various chapters and appendices of this UFC follow.

- Chapter 2 – MODIFICATIONS TO IBC. Chapter 2 provides supplemental requirements for applying the 2024 IBC structural provisions to conventional DoD building design by listing required modifications for specific 2024 IBC sections. The 2024 IBC sections that are not referenced in Chapter 2 or otherwise modified by provisions of Chapter 6 and Appendix B apply as they are written in the 2024 IBC.
- Chapter 3 – MODIFICATIONS TO ASCE 7. Chapter 3 provides supplemental requirements for applying the ASCE 7-22 structural and nonstructural component provisions to conventional DoD building design by listing required modifications for specific ASCE 7-22 sections. The ASCE 7-22 sections that are adopted by the 2024 IBC but are not referenced in Chapter 3 or otherwise modified by provisions of Chapter 7 and Appendix B apply as they are written in ASCE 7-22.
- CHAPTER 4 - EVALUATION AND RETROFIT OF EXISTING BUILDINGS. This chapter contains provisions for the *repair*, *alteration*, change of occupancy, acquisition, *addition* to, and relocation of existing buildings. For seismic evaluation of existing buildings, this chapter adopts by reference the provisions of

ICSSC RP 10, as well as those of ASCE/SEI 41-17. This chapter also makes revisions to specific sections in RP 10. Additionally, this chapter contains modifications to the 2024 IEBC including the scope, and the prescriptive compliance method for nonseismic evaluation of existing buildings.

- **CHAPTER 5 – NONBUILDING STRUCTURES.** This chapter lists the names of various standards and other guidelines to be followed for the design of highway bridges, railroad bridges, tanks for liquid storage, tanks for petroleum storage, environmental engineering concrete structures, prestressed concrete tanks, water treatment facility structures, transmission towers and poles, antenna towers, and pedestrian bridges.
- **CHAPTER 6 – MODIFICATIONS TO THE IBC FOR CRITICAL HEALTHCARE FACILITIES.** This chapter contains a number of additional requirements for certain critical healthcare facilities identified in the chapter. The requirements are presented in the form of modifications to Chapters 16, 18, 19, 20, 21, and 22 of the IBC.
- **CHAPTER 7 – MODIFICATIONS TO ASCE 7 FOR CRITICAL HEALTHCARE FACILITIES.** This chapter contains a number of additional requirements for the same healthcare facilities within the scope of Chapter 6. The requirements are presented in the form of modifications to Chapters 11, 12, and 13 of ASCE 7.
- **Appendix A – BEST PRACTICES.** This appendix provides useful recommendations and guidance on a number of important topics such as building drift limits, impact resistant glazing, wind and seismic loads on photovoltaic arrays, etc.
- **Appendix B – ALTERNATE DESIGN PROCEDURE FOR BUILDINGS AND OTHER STRUCTURES IN RISK CATEGORY IV.** For buildings assigned to Risk Category IV, those that are “essential” because of their military function or post-earthquake recovery role, the 2024 IBC/ASCE 7-22 requires higher design lateral loads and more stringent structural detailing procedures than those for buildings assigned to Risk Category I, II, or III. Applying nonlinear analysis procedures may result in more economical or better-performing Risk Category IV buildings than linear elastic procedures can provide. While the 2024 IBC/ASCE 7-22 permits nonlinear static analysis procedures, it provides little guidance on how to perform them. Appendix B presents optional nonlinear static analysis procedures that may be used for Risk Category IV buildings. Apply the optional nonlinear procedures outlined in Appendix B only with the approval of the Authority Having Jurisdiction.
- **Appendix C – GUIDANCE FOR SEISMIC DESIGN OF NONSTRUCTURAL COMPONENTS.** Appendix C provides guidance for seismic design of nonstructural components. Requirements for design of nonstructural components in this UFC are supplemented by guidance provided in this appendix.

- Appendix D – MECHANICAL AND ELECTRICAL COMPONENT CERTIFICATION. Appendix D provides guidance in addition to what is available in ASCE 7-22 Section 13.2.2 on certification of mechanical and electrical components.
- Appendix E – MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS, L_o , AND MINIMUM CONCENTRATED LIVE LOADS. This appendix contains Table E-1, which replaces Table 1607.1 of the 2024 IBC and includes additional occupancy or use classification for military facilities that are shown in bold italics.
- Appendix F - GUIDANCE FOR COMPOSITE TECHNOLOGIES FOR BRIDGE APPLICATIONS. The fiber reinforced polymer (FRP) technologies covered in this Appendix include carbon FRP composite prestressing systems, FRP composite external strengthening and repair systems, and FRP composite elements including bridge piles and bridge decks. This appendix also includes information on thermoplastic materials for replacement of timber bridges including thermoplastic lumber, thermoplastic piles, and thermoplastic I-beams.
- Appendix G – GLASS FIBER-REINFORCED POLYMER (GFRP) BARS FOR CONCRETE STRUCTURES. This appendix provides design resources to structural engineers interested in using glass fiber-reinforced polymer (GFRP) reinforcement in concrete structures. New standards developed by ASTM and ACI for GFRP bars are discussed along with other supporting guides and reports. This appendix identifies the limits on the use of GFRP reinforcement in concrete structures and key design considerations.
- Appendix H – GLOSSARY. This appendix lists all the abbreviated terms used in this UFC.
- Appendix I – REFERENCES. The UFC has an extensive list of referenced public documents. The primary references for this UFC are the 2024 IBC and ASCE 7-22.

1-7 COMMENTARY.

Limited commentary has been provided in the chapters. Section designations for such commentary are preceded by a “[C]”, and the commentary narrative is shaded.

1-8 OTHER CRITERIA.

Military criteria other than those listed in this document may be applicable to specific types of structures. Such structures must meet the additional requirements of the applicable military criteria.

1-8.1 General Building Requirements.

Comply with UFC 1-200-01, *DoD Building Code*. UFC 1-200-01 provides applicability of model building codes and government unique criteria for typical

design disciplines and building systems, as well as for accessibility, antiterrorism, security, high performance and sustainability requirements, and safety. Use this UFC in addition to UFC 1-200-01 and the UFCs and government criteria referenced therein.

1-8.2 Progressive Collapse Analysis and Design.

When required, apply UFC 4-023-03, *Design of Buildings to Resist Progressive Collapse*.

1-8.3 Design of Risk Category V Structures.

A risk category not included in the 2024 IBC/ASCE 7-22, Risk Category V, has been added to address national strategic military assets. Structures in this risk category are designed to remain elastic during the MCE_R . Refer to Table 2-2 of this UFC for the list of structures that must be assigned to RC V. Refer to UFC 3-301-02 for the design of all RC V structures.

1-8.4 Cybersecurity.

All facility-related control systems (including systems separate from a utility monitoring and control system) must be planned, designed, acquired, executed, and maintained in accordance with UFC 4-010-06, and as required by individual Service Implementation Policy.

1-9 REFERENCES.

APPENDIX I contains a list of references used in this document. The publication date of the code or standard is not included in this document. Unless otherwise specified, the most recent edition of the referenced publication applies.

This Page Intentionally Left Blank

CHAPTER 2 MODIFICATIONS TO IBC

2-1 IBC CHAPTER 1 - SCOPE AND ADMINISTRATION.

2-1.1 Section 101 – GENERAL.

101.4.7 – Existing Buildings [Replacement]

For seismic evaluation and retrofit of existing buildings, the provisions of Chapter 4 of this UFC apply to all matters governing the *repair, alteration, change of occupancy*, acquisition, *addition* and relocation.

For nonseismic evaluation and retrofit of existing buildings, the provisions of the *International Existing Building Code*, as modified by Chapter 4 of this UFC, shall apply to matters governing the *repair, alteration, change of occupancy, addition* to and relocation of *existing buildings*.

[C] 101.4.7 – Existing Buildings [Replacement]

The purpose of this [Replacement] is to direct users to specific provisions for seismic evaluation and retrofit of existing buildings. Chapter 4 of this UFC cites a federal recommended practice document (ICSSC RP 10) and a national standard (ASCE 41-17) for seismic evaluation and retrofit of existing buildings. The chapter provides some modifications and clarifications to the requirements of RP 10 and ASCE 41-17.

Additionally, nonseismic retrofit provisions included in Chapter 4 of this UFC are also referenced here.

2-1.2 Section 116 - UNSAFE STRUCTURES AND EQUIPMENT.

116.5 – Restoration or Abatement [Replacement]

Where the structure or equipment determined to be unsafe by the AHJ is restored to a safe condition, the owner, the owner's authorized agent, operator or occupant of the structure, premises or equipment deemed unsafe must abate or cause to be abated or corrected such unsafe conditions by repair, rehabilitation, demolition or other approved corrective action. To the extent that *repairs, alterations* or *additions* are made or a change of occupancy occurs during the restoration of the structure, such *repairs, alterations, additions* or *change of occupancy* must comply with the requirements of Sections 101.4.7 of this UFC.

2-2 IBC CHAPTER 2 – DEFINITIONS.

2-2.1 Section 202 – DEFINITIONS.

STRUCTURAL ENGINEER OF RECORD (SER) [Addition]

The Structural Engineer of Record (SER) is a registered design professional who performs, supervises, or approves the analysis, design, and document preparation for the building structural system. The SER is responsible for the design of the structural system, which is the completed combination of elements that serves to support the building's self-weight, superimposed dead loads, applicable live loads, and environmental loads such as wind, seismic, and thermal.

2-3 IBC CHAPTER 4 – SPECIAL DETAILED REQUIREMENTS BASED ON OCCUPANCY AND USE.

2-3.1 Section 423 – STORM SHELTERS.

423.4 – Critical Emergency Operations [Supplement]

The requirements of this section shall also apply to hurricane-prone regions (see ASCE 7 Section 26.2) and to facilities housing critical national defense functions that must be manned continuously and for which there is no redundant capability at a different location.

423.5 – Group E occupancies. [Supplement]

Delete Exception 1. Renumber Exceptions 2 and 3 as Exceptions 1 and 2 respectively.

Group E day care facilities shall include Child Development Centers (CDCs), even if classified as Group I-4, as defined by the army, the navy, the air force, the marine corps, and other branches of the military for their respective purposes.

2-4 IBC CHAPTER 16 – STRUCTURAL DESIGN.

2-4.1 Section 1603 – CONSTRUCTION DOCUMENTS.

1603.1.5 – Earthquake Design Data Item 3. [Replacement]

3. Spectral response acceleration parameters, S_s and S_1 . If the data are based on site-specific response analysis, this must be noted. Site-specific source data must also include whether response spectrum or time-history analyses were performed.

1603.1.10 – Systems/Components Requiring Special Inspection for Seismic Resistance [Addition]

Construction documents and specifications must be prepared for those systems and components requiring special inspection for seismic resistance, as specified in 2024 IBC Section 1705.13 as modified by the appropriate special inspection section in UFC 1-200-01 and by the SER. Reference to seismic standards in lieu of detailed drawings is acceptable.

1603.2 – Delegated Engineered Systems [Addition]

The SER for a structure may delegate responsibility for the design of systems or components of the structure to a qualified registered professional engineer. Both the SER for the structure and the engineer receiving such delegation must comply with the requirements of this UFC.

Exception: The SER must design and detail all lateral force-resisting system connections for wind and seismic forces, including steel connections. This provision does not preclude a pre-engineered building engineer from designing primary lateral force-resisting connections where said engineer is the building SER. This would be the case with pre-engineered metal buildings and pre-engineered parking garages for example.

The following are some examples of optional delegated designs:

- a. Pre-fabricated wood components (e.g. pre-engineered trusses)
- b. Cast-in-place post-tensioned concrete structural systems
- c. Precast, prestressed concrete components
- d. Open web steel joists and joist girders
- e. Specialty foundation systems
- f. Simple (shear only) steel connections (lateral force-resisting system connections must be designed by SER)
- g. Cold-formed steel joist/stud/truss framing and pre-fabricated components
- h. Seismic design and anchorage of nonstructural components
- i. Proprietary track for under-hung cranes and monorails
- j. Cross-laminated timber connections (lateral force-resisting system connections must be designed by SER)

The engineer to whom design responsibility has been delegated must sign and seal all work they design. The SER must review all submittals that have been signed and sealed by the delegated engineer to verify compliance with the design intent and the specified design criteria and to ensure coordination with the contract documents and other shop drawings. All submittals from the engineer to

whom design responsibility has been delegated must be approved by the SER prior to the start of fabrication of the system or component and prior to any field construction that may be affected by the system or component.

2-4.2 Section 1604 - GENERAL DESIGN REQUIREMENTS.

1604.3 - Serviceability [Supplement]

The SER must ensure that the maximum allowable frame drift is suitable for the proposed structure considering occupancy, use/function, and all details of construction. See ASCE 7-22 Appendix C “Serviceability Considerations” including commentary, and Section A-1.1 of UFC 3-301-01 for additional guidance.

1604.3.1 - Deflections [Replacement]

Deflections of structural members must not exceed the most restrictive of the limitations of: (1) Sections 1604.3.2 through 1604.3.5, (2) those permitted by Table 1604.3, or (3) those permitted by Table 2-1 of UFC 3-301-01.

Table 2-1 \4\ /4/ Wind Induced Deflection Limits for Framing Supporting Exterior Wall Finishes ^{a,b}

Brick veneer	$L/600$
Exterior Insulation Finish Systems	$L/240$
Cement board	$L/360$
Stone Masonry	VERIFY WITH STONE SUPPLIER
Plywood and Wood-Based Structural-Use Panels	$L/240$
Gypsum sheathing	$L/240$
Metal or vinyl siding and insulated metal panel	$L/120$

\4\ /4/

- a. The wind load is permitted to be taken as 0.42 times the “component and cladding” wind loads for the purpose of determining the deflection limits herein.
- b. L must be calculated as $L = kl$, where k is the theoretical effective length factor, and l is length of the member between supports.

Table 1604.5 [Replacement]

Replace Table 1604.5 of the IBC with Table 2-2 of this UFC. All references in the IBC to Table 1604.5 must be interpreted as a reference to Table 2-2 of this UFC. Items that are different from those in 2024 IBC Table 1604.5 are shown in *italics*.

Table 2-2 Risk Category of Buildings and Other Structures

Risk Category	Nature of Occupancy	Seismic Factor I_e			Tsunami Factor I_{tsu}	DoD Sea Level Rise (SLR) Scenario ^f
I	Buildings and other structures that represent a low hazard to human life in the event of failure, including, but not limited to: <ul style="list-style-type: none"> • Agricultural facilities • Certain temporary facilities • Minor storage facilities 	1.00			N/A <i>Tsunami design not required</i>	N/A

Notes to Table 2-2, “Risk Category of Buildings and Other Structures”

- a. For purposes of occupant load calculations, occupancies required by *IBC* Table 1004.5 to use gross floor area calculations shall be permitted to use net floor areas to determine the total occupant load. The floor area for vehicular drive aisles shall be permitted to be excluded in the determination of net floor area in parking garages.
- b. Where approved by the *AHJ*, the classification of buildings and other structures as Risk Category III or IV based on their quantities of toxic, highly toxic or explosive materials is permitted to be reduced to Risk Category II, provided that it can be demonstrated by a hazard assessment in accordance with ASCE 7 Section 1.5.3 that a release of the toxic, highly toxic or explosive material is not sufficient to pose a threat to the public.
- c. *Risk Category V has been added to address national strategic military assets. Structures in this risk category are designed to remain elastic during the MCE_R. Refer to UFC 3-301-02 for the design of all RC V structures.*
- d. *These facilities may be designed for Tsunami Risk Category I or II as approved by the AHJ.*
- e. *These facilities may be designed for Tsunami Risk Category I, II or III as designated by the AHJ if adequate equivalent facilities are available*

outside of the tsunami inundation zone or if adequate equivalent facilities within the inundation zone have been designed for the effects of tsunami.

- f. *Use the site-specific value from the DoD Regional Sea Level (DRSL) database corresponding to the designated scenario (low/medium/high/highest) for the year 2065. The DRSL database is available at <https://sealevelscenarios.serdp-estcp.org>*
- g. *Subject to approval by the AHJ, a DoD 2065 sea level rise scenario of Medium may be used for Risk Category IV and V structures when designing for a combination of tsunami and sea level rise. Reference Section 3-3.1 within this UFC for specific limitations and requirements.*
- h. *14\ Defense Critical Assets must be explicitly listed in the OSD approved Mission Assurance tracking system. See DODI 3020.40 and 3020.45. The list of specific DCA's must follow the appropriate classification guidance. 14/*

1604.12 - Expansion Joints [Addition]

See guidance in “Design of Concrete Floor Slabs-on-Ground for DoD Facilities” posted under Related Materials for this UFC on the WBDG.

2-4.3 Section 1605 – LOAD COMBINATIONS.

1605.1.2 – Structural Members Sensitive to Vertical Ground Motion [Addition]

Where the design earthquake spectral response acceleration parameter at short periods, S_{DS} , is greater than 0.6g, the components of building and nonbuilding structures listed below must be designed for additional load combinations given in Sections 2.3.6 and 2.4.5 in Chapter 3 of this UFC for Strength Design and Allowable Stress Design, respectively.

Building Structures:

- horizontal or nearly horizontal structural members spanning 65 ft or more
- horizontal or nearly horizontal cantilever components longer than 16 ft
- horizontal or nearly horizontal prestressed components
- building components, excluding foundations, in which demands due to gravity loads exceed 80% of the nominal strength of the component
- horizontal structural elements supporting discontinuous vertical elements of the gravity load-resisting system
- base-isolated structures

Nonbuilding Structures:

- long-span roof structures (e.g., stadiums or aircraft maintenance hangar header truss)
- electric power generation facilities

Exception: Nonbuilding structures addressed by ASCE 7-22 Section 15.1.4 are not required to comply with this section.

[C] 1605.1.2 Structural Members Sensitive to Vertical Ground Motion [Addition]

The effects of vertical earthquake ground motion on buildings have traditionally been given much less attention than the effects of horizontal ground motion. This is largely due to the belief that the peak vertical ground acceleration is considerably smaller than the peak horizontal ground acceleration. A fairly large safety factor against static vertical loads also exists in engineered buildings. As a result, it is generally considered adequate to include the effects of vertical ground motions in the simplified form of $0.2S_{DS}D$, as done in the IBC and the ASCE 722 standard for many years. However, certain structural members are particularly vulnerable to vertical ground motions and require more explicit consideration of such ground motions in their design. This [Addition] addresses those specific members by incorporating additional provisions for design considering vertical ground motions.

The threshold value of $S_{DS} > 0.6g$ was derived from a similar requirement in the 2004 edition of Eurocode 8, which specified the peak vertical ground acceleration, a_{vg} , to be greater than $0.25g$ for its special provisions related to vertical ground motions to apply. The derivation is as shown below:

1. From the vertical ground motion response spectrum given in ASCE 7-22 Section 11.9.2, the ratio of the peak vertical ground acceleration (spectral acceleration at $T_v = 0$) and the maximum vertical spectral acceleration (flat top portion of the response spectrum) is $0.65/1.05 = 0.62$.
2. The maximum vertical spectral acceleration has been traditionally assumed to be $2/3S_{DS}$.
3. So, the peak vertical ground acceleration can be expressed in terms of S_{DS} as:
 $a_{vg} = 0.62 \times (2/3S_{DS}) = 0.41S_{DS}$
4. So, $a_{vg} > 0.25g \Rightarrow S_{DS} > 0.6g$

1605.2 – Alternative Allowable Stress Design Load Combinations [Deletion]

Delete this section in its entirety.

2-4.4 Section 1607 - LIVE LOADS.

1607.1 - General [Replacement]

Live loads are those loads defined in Section 1607.1. Table E-1 of this UFC defines minimum uniformly distributed live loads and minimum concentrated live loads for the design of structures. Table E-1 is IBC Table 1607.1 with additional Occupancy or Use classifications for military facilities. The classifications that have been added to IBC Table 1607.1 are shown in bold italics within Table E-1.

Table 1607.1 [Replacement]

Replace Table 1607.1 of the IBC with Table E-1 of this UFC. (All references in the IBC to Table 1607.1 must be interpreted as references to Table E-1 of this UFC.)

1607.8.1 - Loads [Replacement]

Where a structure does not restrict access for vehicles that exceed a 10,000 pound (4536 kg) gross vehicle weight rating, those portions of said structure subject to such loading must be designed using the vehicular live loads, including consideration of impact and fatigue, in accordance with the AASHTO Bridge Design Specification.

1607.12.4 – Fall arrest and lifeline, and rope descent system anchorages [Replacement]

The applied 3100-pound load is a live load to be used with either the load combinations for allowable stress design or the load combinations for strength design.

To protect personnel during occupancy and maintenance phases, consider fall hazards at the planning and design phase of a project and eliminate them to the maximum extent possible. Also consider safe access to work location at heights.

When elimination or prevention of fall hazards is not feasible, include in design certified and labeled anchorages that are conveniently located to perform the work safely.

Where fall protection is required near weight-handling equipment, prevent conflicts between the weight-handling equipment and fall protection measures.

1607.12.5 - Hangars [Addition]

In hangars, where horizontal lifelines are used as the fall protection solution for aircraft maintenance, make sure that there will be no interference between the crane envelope inside the hangar and the horizontal lifeline system.

14\ 1607.14 – Bridge Crane Support Structure [Addition]

Reference AISC Design Guide 7, Section 18 for design of crane supporting structure, including crane support beams (runway beams).

For seismic design categories C-F see 3-7.6 13.6.14 /4/

2-4.5 Section 1608 - SNOW LOADS.

1608.2 - Ground Snow Loads [Replacement]

Ground snow loads at DoD installations within the United States and its territories and possessions must be determined using the ASCE Hazard Tool hosted at

<https://ascehazardtool.online>

Snow loads are zero for Hawaii, except in mountainous regions as approved by the AHJ.

At locations where the ground snow load is not provided by the ASCE Hazard Tool, consult the AHJ.

1608.2.2 - Specific Locations Outside of the United States [Addition]

Ground snow loads at specific locations outside of the United States and its territories and possessions are identified using a spreadsheet that can be found on the Whole Building Design Guide Structural Engineering UFC Page as a related item for download

At locations where the ground snow load is not provided, use the best locally available information.

1608.2.3 - Snow Load Case Studies [Addition]

Snow load case studies may be done to clarify and refine snow loadings at site-specific locations with the approval of the AHJ. Where required by the AHJ, a site-specific study must be conducted. The ground snow load is to be determined based on an RC II structure for this purpose. The methodology used to conduct snow load case studies at site-specific locations is presented in the Cold Regions Research and Engineering Laboratory (CRREL) report "Database and Methodology for Conducting Site Specific Snow Load Case Studies for the United States." by Tobiasson and Greatorex and "Site-Specific Case Studies for Determining Ground Snow Loads in the United States" by Buska, Greatorex, and Tobiasson.

2-4.6 Section 1609 - WIND LOADS.

1609.1.1 – Determination of Wind Loads [Supplement]

Add the following to the list of exceptions:

8. For winds parallel to the ridge of open buildings, the wind load delivered to the main wind force resisting system from the bare frames or partially clad end walls must be determined in accordance with the provisions of ASCE 7-22 Section 28.3.7.

1609.1.2 – Aircraft Hangar Wind Loads [Addition]

Wind load on the main wind force resisting system ~~and~~ and components and cladding ~~of~~ of aircraft hangars must be determined based on the following conditions:

- Hangar doors closed for winds at the maximum design velocity. Calculate the structural forces based upon the assumption of a “partially enclosed building.” It is permissible to use the large volume reduction factor of ASCE 7 in determining the design wind pressures. Assume that a 1-inch (25-mm) strip around the perimeter of all hangar door panels is an opening and combine this with the area of all unshielded fenestration.
- Hangar doors open to the maximum extent possible with a design wind velocity of 60 mph (97 km/h). Calculate the structural forces upon the assumption of a “partially enclosed building.” Use the total open-door area in the large volume reduction factor calculation.

1609.2.3 – Vertical Lift Fabric Hangar Doors (VLFD) [Addition]

Vertical Lift Fabric Doors are prohibited within windborne debris regions.

Additionally, VLFD's are prohibited for use in aircraft maintenance hangars where 700-year-MRI wind speeds (IBC Figure 1609.3(2), ASCE 7 Figure 26.5-1B) equal or exceed wind speeds defining a windborne debris region, namely, 130 mph (58 m/s) within one mile of the coastal mean high-water line where an Exposure D condition exists upwind of the waterline or 140 mph (63.6 m/s) anywhere else.

[C] 1609.2.3 – Vertical Lift Fabric Hangar Doors (VLFD) [Addition]

VLFD's are currently prohibited for use in windborne debris regions defined in the IBC due to failures experienced during hurricane Michael. These failures were predominately caused by wind driven debris.

Additionally, DoD has prohibited VLFD use in locations where the 700-year-MRI wind speed exceeds the threshold wind speed for windborne debris regions. This is because the risk of damage caused by windborne debris is the same in these areas as in windborne debris regions. In essence, this has served to slightly expand windborne debris regions as defined in the IBC.

1609.2.4 – Roll Up Doors and Sectional Doors in Hurricane Prone Regions [Addition]

In hurricane prone regions, warehouse and/or garage roll up doors or sectional doors must be pressure tested for components and cladding design wind pressure and shown to pass in accordance with ANSI/DASMA 108, *Standard Method for Testing Sectional Garage Doors and Rolling Doors*. This requirement must be noted on the construction drawings in addition to the project specifications. The SER must specify the components and cladding design wind pressure for garage/sectional doors on the construction drawings.

1609.3.1 - Wind Speed Conversion [Replacement]

When required, the basic wind speed can be converted to an allowable stress design wind speed, V_{asd} , using Equation 16-18a.

$$V_{asd} = \sqrt{0.6} V \quad (\text{Equation 16-18a})$$

When required, the basic wind speed can be converted to a fastest-mile wind speed, V_{fm} , using Equation 16-18b.

$$V_{fm} = (\sqrt{0.6} V - 10.5) / 1.05 \quad (\text{Equation 16-18b})$$

1609.3 - Basic Wind Speed [Replacement]

Basic wind speeds at DoD installations within the United States and its territories and possessions must be determined using the ASCE Hazard Tool hosted at:

<https://ascehazardtool.org>

At locations where the basic wind speed is not provided by the ASCE Hazard Tool, consult the AHJ. The basic wind speeds, V , determined by the AHJ must be in accordance with Chapter 26 of ASCE 7.

1609.3.2 - Specific Locations Outside of the United States [Addition]

Basic wind speeds at specific locations outside of the United States and its territories and possessions can be identified using a spreadsheet that can be found on the Whole Building Design Guide Structural Engineering UFC Page as a related item for download

At locations where the basic wind speed is not provided, use the best locally available information.

1609.3.3 – Design Wind Speed for Non-permanent Structures [Addition]

For **Non-permanent** Structures, as defined in UFC 1-201-01, it is permissible to multiply the basic wind speed, V , as identified in UFC 3-301-01, by a reduction factor of 0.78.

This section supersedes Section 3-2.1.5 of UFC 1-201-01 and IBC Section 3103.6.1.2.

[C] 1609.3.3 – Design Wind Speed for Non-permanent Structures [Addition]

For the purpose of determining design wind speeds for non-permanent structures with design life of 5 years or less, UFC 1-201-01, 4 March 2022, Change 4, 8 August 2023, permits application of a 0.78 reduction factor to the design wind speeds determined in accordance with UFC 3-301-01 for regular structures. However, that allowance is restricted to non-hurricane prone regions only. This [Addition] revises that provision to expand the applicability of the 0.78 factor to hurricane prone regions as well.

The revision was based on a study that looked at design wind speeds at a large number of locations across the United States using a “uniform hazard” approach. For a given risk category of a non-permanent structure, wind speeds were determined for the same probability of exceedance in 5 years as that used in ASCE 7 for a 50-year design life of regular structures. For example, in ASCE 7, the design wind speed values for RC II structures are based on a return period of 700 years, which translates to about 7% probability of exceedance in 50 years. Assuming the same level of wind hazard is acceptable for a non-permanent structure over its 5-yr design life, i.e., a 7% probability of exceedance in 5 years, wind speeds for non-permanent structures assigned to Risk Category II should be determined based on 70-yr wind events. Similarly, design wind speeds for non-permanent structures assigned to Risk Category I, III, and IV need to be determined based on 30, 170 and 300-yr return period wind events, respectively. These can be determined through interpolation using the 300-yr wind speeds given in ASCE 7 Chapter 26 and 25-, 50-, and 100-yr wind speeds given in ASCE 7 Appendix CC, where the return periods are expressed on a log scale.

It was found that, wind speeds determined as described above for a total of 342 locations in the United States matched very closely with the wind speeds determined by simply reducing the ASCE 7 values by a factor of 0.78 as permitted in UFC 1-201-01. And this was seen to be as true for hurricane prone regions as it was for non-hurricane prone regions. As a result, the 0.78 factor is retained for the sake of simplicity, but its applicability is expanded to hurricane prone regions.

For a more detailed discussion on this change, please refer to the report produced by S. K. Ghosh Associates LLC titled “An Evaluation of the Wind and Seismic Provisions of UFC 1-201-01 for Temporary Structures”.

The 2024 IBC has introduced a new Section 3103.6.1.2 for determining the basic wind speeds for non-permanent structures. This section in the UFC supersedes that IBC section.

2-4.7 Section 1613 - EARTHQUAKE LOADS.

1613.1 – Scope [Supplement]

For all structures, wherever ASCE 7-22 Table 12.2-1 is referenced, it must be replaced by Table 3-1 of this UFC.

[C] 1613.1 – Scope [Supplement]

Although Chapter 14 of ASCE 7-22 is not adopted by the 2024 IBC, occasional references to ASCE 7-22 Chapter 14 sections are made in this UFC.

1613.1.1 - Seismic Ground Motion Values [Replacement]

Seismic multi-period response spectra at DoD installations within the United States and its territories and possessions must be determined using the ASCE Hazard Tool hosted at

<https://ascehazardtool.org>

At locations where the seismic parameters are not provided by the ASCE Hazard Tool, consult the AHJ.

1613.1.1.1 - Specific Locations Outside of the United States [Addition]

Seismic ground motion parameters at specific locations outside of the United States and its territories and possessions can be identified using a load spreadsheet posted for download on the Whole Building Design Guide Structural Engineering UFC page (UFC 3-301-01)

For locations not shown, contract the Structural Criteria Working Group member for your service branch.

1613.1.1.2 – Site Specific Seismicity Study Process [Addition]

The site-specific ground motion procedures in Chapter 21 of ASCE 7 may be used to determine ground motions for any structure.

1613.1.1.3 – Ground Motion Parameters for Non-Permanent Structures [Addition]

For Non-permanent Structures, as defined in UFC 1-201-01, it is permissible to use the BSE-1E level response spectra obtained from the ASCE Hazard Tool, which correspond to a seismic hazard of 20% probability of exceedance in 50 years. The link to ASCE Hazard Tool is provided below:

<https://ascehazardtool.org>

The rest of the seismic design, including determination of Seismic Design Category, is to be performed as required by the IBC and ASCE 7 and as modified by this UFC, based on these reduced ground motion values.

This section supersedes Section 3-2.1.6 of UFC 1-201-01 and IBC Section 3103.6.1.4.

[C] 1613.2.1.4 – Ground Motion Parameters for Non-Permanent Structures [Addition]

For the purpose of determining design seismic loads for non-permanent structures with design life of 5 years or less, UFC 1-201-01, 4 March 2022, Change 4, 8 August 2023, permits application of a 0.6 reduction factor to the design seismic loads determined in accordance with UFC 3-301-01 for regular structures. In addition, that allowance is restricted to regions of low seismicity only. This [Addition] revises that provision based on a “uniform hazard” approach that applies to all locations, and that is more consistent with the way all seismic requirements are specified for regular structures.

Ground motion spectral response values that form the basis of seismic design of regular structures (50-yr design life) in this UFC correspond to a seismic hazard of 2% probability of exceedance in 50 years. In other words, it is deemed adequate to design a structure for a seismic hazard that has a 2% probability of exceedance in the structure’s design life. The same criterion could be applied to non-permanent structures as well where it should be adequate to design the structure for a reduced seismic hazard of 2% probability of exceedance in 5 years. In 50-yr term, a 2%-in-5-yr hazard translates to a 20%-in-50-yr hazard.

This [Addition] also allows the use of the same reduced hazard ground motion parameters for the purpose of all seismic design requirements, including determination of Seismic Design Category, for non-permanent structures. As a result, the adoption of a reduced hazard not only reduces the seismic forces, but also leads to less stringent seismic design and detailing requirements for non-permanent structures.

Note that in ASCE 7-10 a switch was made from uniform hazard MCE ground motion to risk-targeted MCE_R ground motion as the basis of design. However, the magnitudes of the two at a particular location are not sufficiently different to

warrant a change in the recommendation to use of 20%-in-50-yr ground motion for non-permanent structures.

For a more detailed discussion on this change, please refer to the report produced by S. K. Ghosh Associates LLC titled “An Evaluation of the Wind and Seismic Provisions of UFC 1-201-01 for Temporary Structures”.

The 2024 IBC has introduced a new Section 3103.6.1.4 for determining the ground motion values for non-permanent structures. This section in the UFC supersedes that IBC section.

1613.4 – Ballasted Photovoltaic Panel Systems [Replacement]

Ballasted photovoltaic panel systems are not permitted.

[C] 1613.4 – Ballasted Photovoltaic Panel Systems [Replacement]

Ballasted systems are specifically disallowed by UFC 3-110-03, *Roofing*.

1613.7 - Procedure for Determining MCE_R and Design Spectral Response Accelerations [Addition]

Ground motion accelerations, represented by response spectra, must be determined in accordance with the procedure of ASCE 7-22 Sections 11.4.2-11.4.6, as modified by Chapter 3 of this UFC, or the site-specific procedure required by ASCE 7-22 Section 11.4.8 as modified by Section 3-5.3 of this UFC.

Subject to approval by the AHJ, a site-specific response analysis using the procedure of ASCE 7-22 Chapter 21 may be used in determining ground motions for any structure. Such analysis needs to include justification for its use in lieu of the ground motion data provided by ASCE 7.

A site response analysis using the procedures of ASCE 7 Section 21.1 must be used for structures on sites classified as Site Class F (see ASCE 7 Section 20.2.1), unless at least one of the following conditions is applicable:

1. The structure is exempted from site response analysis requirement in accordance with ASCE 7 Section 20.2.1.
2. The Risk-Targeted Maximum Considered Earthquake (MCE_R) spectral response acceleration at short periods, S_s , and the mapped MCE_R spectral response acceleration at 1-second period, S_1 , as determined in accordance with UFC 3-301-01, are less than or equal to 0.25 and 0.10, respectively.

S_s and S_1 must be determined for installations within the United States from Section 1613.1.1, added by this UFC. For installations located outside the United

States, S_s and S_1 must be determined from Section 1613.1.1.1, added by this UFC.

2-4.8 Section 1615 – TSUNAMI LOADS.

1615.1 – General [Replacement]

The design and construction of buildings and structures located in a Tsunami Design Zone, as defined by the Tsunami Design Geodatabase or by DoD tsunami mapping for at risk OCONUS installations, must be in accordance with Chapter 6 of ASCE 7, as modified by Section 3-3 of this UFC.

For at risk Pacific and Pacific Rim OCONUS installations, see the following link to access tsunami inundation and flow maps:

<https://www.wbdg.org/dod/ufc/tsunami-inundation-mapping>

Maps are formatted as KMZ files, which can be downloaded and opened with Google Earth, ARCGIS, or an equivalent KMZ compatible geo map application.

2-4.9 Section 1616 – STRUCTURAL INTEGRITY [Deletion].

Delete this section in its entirety.

2-5 IBC CHAPTER 17 - SPECIAL INSPECTIONS AND TESTS.

2-5.1 Section 1701 – GENERAL.

1701.1 - Scope [Supplement]

Add the following paragraph:

Contractual relationships and the composition of the architect / engineer / construction (AEC) team differ from those contemplated by the language of the IBC, when doing DoD construction. When performing design or construction using typical methods for in-house design, AE design, and contracting for construction, IBC/ASCE 7 terms of Authority Having Jurisdiction and Building Official must be as defined in MIL STD 3007

Unless noted otherwise, apply the following substitutions for implementing the IBC:

- “Building official” - defined as “Authority Having Jurisdiction” as referenced in MIL STD 3007).
- “Owner” - defined as “Authority Having Jurisdiction”
- “Permit applicant” - defined as “contractor”

[C] 1701.1 - Scope [Supplement]

The context of the IBC terms “permit”, “permit application”, “permit applicant”, and “owner” must be modified for DoD projects. DoD functions as the building department/jurisdiction and the AHJ functions as the building official. When DoD advertises a project, the building permit is effectively implied/granted. However, the overall project may still require other permits related to site storm water, air quality, demolition disposal, etc.

2-5.2 Section 1703 – APPROVALS.

1703.4 - Performance [Replacement]

New, unusual, or innovative materials, systems or methods previously untried may be incorporated into designs when evidence shows that such use is in the best interest of the Government from the standpoint of economy, lower life-cycle costs, and quality of construction. Supporting data, where necessary to assist in the approval of materials or assemblies not specifically provided for in the code, must consist of valid evaluation reports from International Code Council – Evaluation Service (ICC-ES), or other qualified testing and evaluation service with the prior approval of the AHJ.

1703.4.1 - Research and Investigation [Deletion]

Delete this section in its entirety.

1703.4.2 - Research Reports [Deletion]

Delete this section in its entirety.

2-5.3 Section 1704 – SPECIAL INSPECTIONS AND TESTS, CONTRACTOR RESPONSIBILITY, AND STRUCTURAL OBSERVATIONS.

1704.2.3 Statement of special inspections. [Replacement]

Replace the first paragraph with the following:

The SER must submit a Statement of Special Inspections in accordance with Section 107.1. This statement must be in accordance with Section 1704.3. A template ‘Statement of Special Inspections’ and a template ‘Schedule of Special Inspections’ may be downloaded from the Structural Engineering UFC (3-301-01) page on the Whole Building Design Guide.

1704.6 – Structural Observations [Replacement]

Replace the first two sentences with the following:

Where required by the provisions of Section 1704.6.1, structural observations must be performed by the SER or their designated representative who must be a Registered Design Professional. Structural observation does not include or waive the responsibility for the inspections in Section 110 or the special inspections in Section 1705 or other sections of this code.

1704.6.1 – Structural Observations for Structures [Replacement]

Replace Item 1 with the following:

1 - The structure is classified as Risk Category III or IV in accordance with Table 2-2 of this UFC.

Replace Item 4 with the following:

4 – Such observation is required by the SER.

1704.7 – Special Inspector of Record [Addition]

When the provisions of Section 1704.6.1 apply, the services of a Special Inspector of Record (SIOR) must be retained by the Contractor as a third-party quality assurance agent (see UFC 1-200-01). The SIOR must be a licensed professional engineer in a state acceptable to the AHJ. The SIOR must submit qualifications to, and be approved by, the AHJ.

1704.7.1 – Duties of the Special Inspector of Record (SIOR) [Addition]

The duties of the SIOR are defined in the following UFGS specification:

Section 01 45 35

1704.7.2 – Final Inspection Report [Addition]

When the work requiring Special Inspections is completed and all nonconforming items are resolved to the satisfaction of the SER, the Contractor needs to notify the SIOR to submit a Final Special Inspection Report to the Contracting Officer, the SER, and the Contractor. The Final Special Inspection Report must attest that Special Inspection was performed on all work requiring Special Inspection and that all nonconforming work and corrections of all discrepancies noted in the daily reports was resolved to the satisfaction of the SER and the Contracting Officer. The Final Special Inspection Report must be signed, dated, and must bear the seal of the SIOR.

2-5.4 Section 1705 – REQUIRED SPECIAL INSPECTIONS AND TESTS.

1705.3.3 – Adhesive Anchors [Addition]

The SER is required to determine the proof load (see ACI 318-19 Section 26.7.1(k)) to be used for field-testing and to indicate in the construction documents which anchors are considered critical for testing.

1705.13.6 – Plumbing, Mechanical and Electrical Components [Supplement]

Add the following before the existing text:

Special inspection and verification are required for Designated Seismic Systems and must be performed as required by the Statement of Special Inspections, and the Schedule of Special Inspections, which must be prepared for each project. Templates for these documents may be downloaded from the Structural Engineering UFC (3-301-01) page on the Whole Building Design Guide.

The SER must prepare a Statement of Special Inspections in accordance with Section 1704 for the Designated Seismic Systems. The Statement of Special Inspections must define the periodic walk-down inspections that must be performed to ensure that the nonstructural elements satisfy life safety mounting requirements. The walk-down inspections must be performed by design professionals who are familiar with the construction and installation of mechanical and electrical components, and their vulnerabilities to earthquakes. The selection of the design professional is subject to the approval of the SER.

Designated Seismic Systems require a final walk-down inspection by the SER. The final review must be documented in a report. The final report prepared by the SER must include the following:

1. Record/observations of final site visit
2. Documentation that all required inspections were performed in accordance with the Statement of Special Inspections.
3. Documentation that the Designated Seismic Systems were installed in accordance with the construction documents and inspected in accordance with the requirements of Chapter 17, as modified by this section.

2-6 IBC CHAPTER 18 - SOILS AND FOUNDATIONS.

2-6.1 Section 1808 – FOUNDATIONS.

1808.4 - Vibratory Loads. [Supplement]

Add the following to the end of the paragraph:

Design foundations in accordance with ACI 351.3R or ACI 351.4R, as applicable, and UFC 3-220-01.

1808.8.2.1 – Reinforcement. [Addition]

For footings over three feet (914 mm) thick, the minimum ratio of reinforcement area to gross concrete area in each direction must be 0.0015, with not less than one-half nor more than two-thirds of the total reinforcement required placed near any one face. Use a bar size no smaller than No. 4 (#13M) with a maximum spacing of 12 inches (305 mm). [See 13.3.4.4 of ACI CODE-318-19].

2-6.2 Section 1809 - SHALLOW FOUNDATIONS.

1809.5.2 - Frost Line Depth. [Addition]

Frost line depth for foundation construction must be specified by the project geotechnical engineer.

1809.5.3 – Footing Depth Considering Frost. [Addition]

Frost line depth for foundation construction must be specified by the project geotechnical engineer.

2-7 IBC CHAPTER 19 – CONCRETE.

2-7.1 Section 1901 – GENERAL.

1901.8 - Construction Joints [Addition]

Provide construction, contraction, and expansion joints in structures in accordance with ACI 224.3R and ACI CODE-318-19, Section 26.5.6.

1901.9 – Lightweight Concrete Water Content [Addition]

All coarse lightweight aggregate used in a concrete mixture must be saturated surface dry prior to mixing. The total allowable water in the concrete mixture must account for the water in the aggregate and admixtures. The water-to-cementitious materials ratio must not exceed 0.50.

1901.10 – Glass Fiber Reinforced Polymer (GFRP) Reinforcement [Addition]

Design and construct structural concrete which utilizes glass fiber reinforced polymer (GFRP) reinforcement in accordance with ACI CODE-440.11-22, *Structural Concrete Reinforced with Glass Fiber-Reinforced Polymer (GFRP) Bars--Code and Commentary*. The use of GFRP reinforcement is preferred where corrosion is a durability concern. GFRP does not corrode making it an economical solution for the structures that require regular repair due to exposure

to salts and seawater. GFRP is also 1/4 of the weight of steel reinforcement, making it easier to transport, handle, and place.

GFRP reinforcement has limitations to consider before using Fire ratings for GFRP in structures are not standardized and are low. For this reason, GFRP reinforcement is:

- Not permitted in structures that have a fire rating above zero. Also not permitted in structures that may not have a fire rating but could collapse due to fire and threaten life safety (for example, GFRP reinforcing not allowed for upper deck of double-deck piers, and comparable structures similarly affected by heat zones).
- Allowed for use in architectural precast concrete; however, all connections must use steel.

Other limitations on the use of GFRP according to ACI CODE-440.11-22:

- Do not use in seismic force-resisting systems of structures assigned to Seismic Design Categories B, C, D, E, and F.
- GFRP is permitted in structural members not part of the seismic force-resisting systems of structures assigned to Seismic Design Categories A, B, and C.
- Not recommended for lightweight concrete due to insufficient research data.
- Prestressed concrete systems are not currently covered.

The limitations on seismic force-resisting systems are because GFRP reinforcement is elastic until failure. The current seismic force-resisting systems are designed to yield in certain regions to dissipate the energy generated by seismic excitation. GFRP reinforcement will be permitted if the reinforcement is designed to remain fully elastic.

Appendix G provides guidance in the design and construction of GFRP in concrete structures.

2-7.2 Section 1903 – SPECIFICATIONS FOR TESTS AND MATERIALS.

1903.4 – Additively Constructed Concrete (3D Printed Concrete) [Addition]

Pursuant to UFC 1-200-01 Section 104.11, concrete produced using additive construction, hereafter referred to as Additively Constructed Concrete (ACC), is allowed as alternative material, design and method of construction when complying with the following requirements and when approved in writing by the

AHJ.

ACC structures are limited to one-story, Risk Category I or II structures in Seismic Design Categories A and B only. Additionally, the following general requirements or limitations apply:

- Unreinforced concrete construction is not allowed
- ACC elements are not allowed as part of the Lateral Force-resisting System (LFRS) in Seismic Design Category B unless LFRS assemblies have been shake table tested with relevant loading or wind loads can be demonstrated to govern over seismic loads using an R -factor of 1.0.
- Provide a full description of concrete mixes, including how mixes will differ from region to region as applicable. Include admixtures in description, where utilized.
- Provide a narrative description of Quality Assurance and Quality Control procedures for concrete placement, including hot and cold weather placement constraints for ACC elements. if applicable
- Maintain minimum cover over reinforcement per ACI 318. Cover shall not consist of printed materials unless demonstrated through testing that ACI 318 development length requirements can be met using applicable load factors.
- Cast-in-place or post-installed anchors must not depend on printed material for shear or tensile strength unless site tested to 150% of design load.
- Diaphragm to wall connections must be shown by calculation or testing to resist in plane and out of plane forces with applicable load factors. Anchorage may not be solely dependent on printed shell material.
- Provide complete design drawings, including connection detailing sufficient to adequately depict continuous vertical and lateral load path to foundation.
- Provide mathematical demand and capacity calculations based on ACI 318 for all applicable ASCE 7 loads and affected elements. Calculations must demonstrate a complete vertical and lateral load path and may not rely on printed shell elements to resist loads except for pure compression. Alternatively, webbing may be employed with shell elements as indicated in the Figure 2-1, but only with third-party load testing validation of composite assemblies for all relevant loading. Load capacity values must be published as part of a third-party testing report and tested assemblies must be applicable to constructed assemblies.

Figure 2-1 Webbing in Shell Elements

- Design must be peer reviewed by the government a minimum of 90 days prior to construction start and will include review by subject matter experts at United States Army Corps of Engineers (USACE) Construction Engineering Research Laboratory (CERL). All comments and concerns must be resolved to the government's satisfaction.

Allowable ACC Elements and Limitations

- ACC is limited to reinforced walls no taller than ten feet, reinforced embedded wall pilasters and non-participating stay-in-place formwork for simple reinforced continuous wall footings.
- Suspended elements, including but not limited to beams, girders, or floor and roof diaphragm elements are not approved for ACC.
- ACC wall elements must consist of two printed concrete face shells acting as stay-in-place forms with a minimum interior core width of four inches and a maximum core width of twelve inches. Provide print stabilizers spanning between face shells to occur at no greater than twelve inches on center horizontally and six inches on center vertically. Provide corner stabilizers spanning from interior wall corners to exterior face shell in both directions (e.g., either side of interior corner). Larger print stabilizer spacing requires print-stability testing.
- Embedded pilasters must consist of printed shells and interior monolithic,

reinforced, cast-in-place concrete cores that are six to eight inches by six to eight inches. Larger sections require print-stability testing.

- Wall cavities adjacent to pilasters that are without webbing or monolithic cast-in-place concrete shall not be permitted unless this portion is considered to be non-structural.

Third Party Independent Testing Requirements

ACC structures must conform to the requirements noted in this section and ICC AC509 - *3D Automated Construction Technology for 3D Concrete Walls*. If AC 509 is in conflict, this UFC supersedes. Compliance to this section must be demonstrated by obtaining an ICC ES evaluation report (or equivalent) that conforms to both ICC-AC509 and the following modifications to ICC-AC509

ICC AC509 4.2.1 [Replacement] Cast specimens for compressive testing shall be tested in accordance with ASTM C31 for monolithically cast portions of wall. Cast specimens following ASTM C31 or ASTM C109 shall be permitted for printable material mixture development only. Prior to construction, conduct compressive strength testing in accordance with ASTM C109 with specimens extracted by saw cutting in accordance with ASTM C42 and prepared to meet planeness requirements according to ASTM C109. Specimens shall capture at least one interface and shall be tested for compression in the directions parallel to print direction, perpendicular to print direction, and transverse to print direction.

ICC AC509 4.2.2 [Replacement] Prior to specimen creation, the flow of the printable material shall be tested in accordance with ASTM C230. For materials that exhibit slump prior to entering the printer, the mix may be tested in accordance with ASTM C143 or C1611. Printable materials shall be tested in accordance to ASTM C230 prior to placement and within 5 minutes after leaving the printer.

ICC AC509 4.2.4 [Replacement] Unconfined compression Strength (UCS) Testing: Shall be performed in accordance with ASTM D2166, with cylindrical specimen sizes representative of the bead geometry, where the diameter or height of the specimen must be at least 5 times the maximum particle size. Prior to construction, the UCS shall be performed at 0, 15, 30, 45, 60, 90, and 120 minutes after mixing and the elastic limit at each age shall be determined. This shall be used to report the time to next layer limit based on weight of successive layers expected. Printable materials shall be tested in accordance with this test method prior to placement during printing and within 5 minutes of leaving the printer.

ICC AC509 4.3.3 [Supplement] Freeze-Thaw specimens of printed materials shall be extracted from printed components through saw cutting in accordance with ASTM C666. Specimen sizes shall be as described in ASTM C666 to include specimens with at least 1 interface on each side

parallel to the length of the specimen and specimens with at least 3 layers perpendicular to the length of the specimen. For regions where freeze-thaw is not a concern this test may be forgone.

ICC AC509 4.4.1 [Replacement] Perform tests on 3D printed specimens in accordance with ASTM C341. Length change specimens of printed materials shall be extracted from printed components. Specimens shall have at least 1 interface on each side parallel to the length of the specimen. Components that will be in contact with soils with high sulfate content or exposed to salts must be tested according to ASTM C1012.

ICC AC509 4.6.2 [Addition] Tensile bond strength shall be in accordance with ASTM C496 or ASTM C1583. Shear bond strength shall be tested as described below.

- 4.6.2.1 Tensile bond strength tested in accordance with ASTM C496 shall use prismatic specimens consisting of at least two layers with a single interface loaded along the interface. Specimens shall be tested transverse to the print with the height being equal to a single shell width, and the height being equal to two times a single shell width, and the length being equal to at least 3 times a single shell width.
- 4.6.2.2 Specimens for direct shear testing shall be loaded in single or double shear using prismatic specimens consisting of at least two layers for single shear and three layers for double shear. Specimens shall have dimensions that are representative of the wall shell dimensions and a length of at least 3 times the shell width. Loading rate shall in accordance to ASTM C496.
- 4.6.2.3 Specimens for interface testing shall be extracted by saw cutting in accordance with ASTM C42 and prepared to meet planeness requirements in ASTM C109.

ICC AC509 4.8 [Addition] For construction geometries, a print stability test must be performed, which consists of a print mock-up representative of the wall geometry used in construction, to ensure that there are no stability issues prior to construction. Time between layers and construction shall be representative of field conditions. This is permitted to be done as part of the development of structural test samples.

ICC AC509 4.9 [Addition] Dynamic Testing

- 4.9.1 Testing for blast overpressure, where applicable, must be in accordance with ASTM F2247 or ASTM F2927 for door locations and ASTM F1642 or GSA TS01 for windows locations. Ballistics testing must be in accordance with MIL STD 662.
- 4.9.2 Wind and seismic testing shall be performed in accordance with

ASTM E2126 procedure for in-plane shear or out-of-plane bending. Where structures must meet seismic categories higher than C, shake table testing shall be performed to meet design requirements.

- 4.9.3 Impact testing shall be performed in accordance with ASTM E1886 for windborne debris and ASTM E695 for impact loading.

ICC AC509 5.5 [Replacement] Special Inspections shall be performed in accordance with this UFC. Quality control testing shall be performed by obtaining samples cured following ASTM C31 for compression testing and interface testing shall be performed according to Sections 4.2 and 4.6. Fresh material testing shall be performed in accordance with ASTM C31, with testing performed in accordance with Sections 4.2.2 and 4.2.4 in place of the slump test.

5.5.1 Representative components for sample extraction shall be printed at the same time as construction of the printed components to be placed in service. Each representative component shall be large enough to extract samples for compliance with Sections 4.2.1, 4.4.1, and 4.6.2.

5.5.2 Data on printing conditions and process shall be documented and reported to include: start times, print time for each layer, delay times (includes waiting between layers), reasons for delays, times at which delays occurred, and hourly temperature and humidity. If delay occurs in the middle of printing a layer, the time prior to delay and following delay should be recorded, in addition to the delay.

2-7.3 Section 1904 - DURABILITY REQUIREMENTS.

1904.3 – Environmental Severity Classification and Concrete Cover [Addition]

Conform to ACI 357.3R Table 5.5.4 for minimum concrete cover for exterior exposed concrete at project locations with an Environmental Severity Classification (ESC) C3 through C5. See UFC 1-200-01 for determination of ESC for project locations. Exposed concrete is any concrete that is not enclosed within a building envelope. In addition, concrete with a minimum of two coats of exterior grade paint is not considered exposed where properly maintained. Corrosion inhibitor coatings/additives would not qualify as a paint coating. This requirement does not apply to galvanized, stainless or epoxy coated reinforcement. Refer to ACI 318 cover requirements in these cases.

2-7.4 Section 1907 -SLABS-ON-GROUND.

1907.3 – Thickness. [Supplement]

Reference guidance in *“Design of Concrete Floor Slabs-on-Ground for DoD Facilities”* under Related Materials for this UFC (WBDG page for 3-301-01).

1907.5 – Slab-on-Ground Design. [Addition]

Slabs-on-ground supporting warehouses must have minimum reinforcement according to UFC 4-440-01.

1907.6 – Slab-on-Ground Over Permafrost. [Addition]

Design and construction of slabs-on-ground over permafrost must be in accordance with UFC 3-130-01.

1907.7 – Post-Tensioned Slab-on-Ground. [Addition]

The design of post-tensioned slabs-on-ground must be in accordance with PTI DC10.1.

2-8 IBC CHAPTER 21 – MASONRY.

2-8.1 Section 2101 – GENERAL.

Renumber Section 2101.2.1 as 2101.2.6.

2101.2.1 - Allowable Stress Design [Addition]

Masonry must be designed as reinforced unless the element is isolated from the structure so that vertical and lateral forces are not imparted to the element.

2101.2.2 - Strength Design [Addition]

Masonry must be designed as reinforced unless the element is isolated from the structure so that vertical and lateral forces are not imparted to the element.

2101.2.3 - Empirical Design [Addition]

Do not design masonry according to the empirical method.

2101.4 - Shear Wall Construction [Addition]

Shear walls must be of running bond construction only; stack bond construction is not permitted.

2101.5 - Prohibition [Addition]

The following material is not permitted:

Celersap (common European in place clay tile forming system for concrete floors)

2-8.2 Section 2104 – CONSTRUCTION.

Renumber Sections 2104.1.1 and 2104.1.2 as 2104.1.4 and 2104.1.5, respectively.

2104.1.1 - Placing Mortar and Units [Addition]

Masonry walls below grade and elevator shaft walls must be grouted solid.

2104.1.2 - Installation of Wall Ties [Addition]

Use of corrugated metal brick ties is not permitted.

2104.1.3 - Joint Reinforcement [Addition]

Horizontal wall reinforcement must be continuous around wall corners and through wall intersections, unless the intersecting walls are separated. Reinforcement that is spliced in accordance with the applicable provisions of TMS 402-22 is permitted to be considered continuous.

2104.1.6 - Concrete Masonry Control Joints [Addition]

Spacing and placement of control joints must be in accordance with NCMA TEK 10-2C or 10-3.

2104.1.7 - Vertical Brick Expansion Joints [Addition]

Spacing, placement, and size of vertical brick expansion joints must be in accordance with BIA Technical Notes 18 and 18A.

2-8.3 Section 2106 - SEISMIC DESIGN.

2106.2 - Additional Requirements for Masonry Systems [Addition]

2106.2.1 - Minimum Reinforcement for Special or Intermediate Masonry Walls, SDC B-F [Addition]

In addition to the minimum reinforcement requirements of Sections 7.3.2.5 and 7.3.2.4 of TMS 402-22, the following applies:

Only horizontal reinforcement that is continuous in the wall or element is permitted to be included in computing the area of horizontal reinforcement. Intermediate bond beam steel properly designed at control joints is permitted to be considered continuous.

2106.2.2 - Joints in Structures assigned to SDC B or Higher [Addition]

Where concrete abuts structural masonry and the joint between the materials is not designed as a separation joint, the concrete must be roughened so that the average height of aggregate exposure is 1/8 in. (3 mm) and must be bonded to the masonry in accordance with these requirements as if it were masonry. Vertical joints not intended to act as separation joints are required to be crossed by horizontal reinforcement as required by Section 5.2.3 of TMS 402-22.

2106.2.3 - Coupling Beams in Structures Assigned to SDC D or Higher [Addition]

Structural members that provide coupling between shear walls must be designed to reach their moment or shear nominal strength before either shear wall reaches its moment or shear nominal strength. Analysis of coupled shear walls must comply with accepted principles of mechanics.

The design shear strength, ϕV_n , of the coupling beams is required to satisfy the following criterion:

$$\phi V_n \geq \frac{1.25(M_{n1} + M_{n2})}{L_c} + 1.4V_g$$

Where:

M_{n1} and M_{n2} = nominal moment strengths at the ends of the beam

L_c = length of the beam between the shear walls

V_g = unfactored shear force due to gravity loads

The calculation of the nominal moment strength needs to include the reinforcement in reinforced concrete roof and floor systems. The width of the reinforced concrete slab used for inclusion of reinforcement must be six times the floor or roof slab thickness.

2106.2.4 - Anchoring to Masonry [Addition]

Anchors in masonry must be designed in accordance with TMS 402-22. Additionally, at least one of the following must be satisfied for structures assigned to SDC C or higher.

- a. Anchors in tension are designed to be governed by the tensile strength of a ductile steel element.
- b. Anchors are designed for the maximum load that can be transmitted to the anchors from a ductile attachment, considering both material overstrength and strain hardening of the attachment.

- c. Anchors are designed for the maximum load that can be transmitted to the anchors by a non-yielding attachment.
- d. Anchors are designed for the maximum load obtained from design load combinations that include E , where the effect of horizontal ground motion, Q_E , is multiplied by Ω_o .

[C] 2106.2.4 - Anchoring to Masonry [Addition]

This [Addition] harmonizes design of anchors embedded in masonry with that of anchors embedded in concrete. These provisions are intended to prevent brittle failure in the connections. ACI 318-19 Chapter 17 includes similar provisions to prevent brittle failure of anchors embedded in concrete. These requirements are simplified versions of those in ACI 318-19. Note Option a is available only for anchors in tension, and not for anchors in shear. Also, Item d requires that the anchor design forces produced by the horizontal ground motions only (Q_E) be multiplied by the overstrength factor Ω_o . Anchor design forces produced by the vertical earthquake ground motions (E_v) do not need to be amplified.

2-8.4 Section 2109 - EMPIRICAL DESIGN OF ADOBE MASONRY [Deletion].

Delete this section in its entirety.

2-9 IBC CHAPTER 22 – STEEL.

2-9.1 Section 2201 – GENERAL.

2201.4 – Connections [Supplement]

Add the following to the end of the paragraph:

Compressible-washer-type direct tension indicators or twist-off-type tension-control bolts conforming to Research Council on Structural Connections (RCSC) *Specification for Structural Joints Using High-Strength Bolts* must be provided at all high-strength bolted connections.

2-9.2 Section 2202 - STRUCTURAL STEEL AND COMPOSITE STRUCTURAL STEEL AND CONCRETE.

2202.1 – General [Supplement]

Add the following to the end of the paragraph:

Design structural steel floor framing systems for vibration serviceability in accordance with AISC Design Guide 11.

2202.3 – Steel Structures in Corrosive Environments [Addition]

Protect exposed steel in corrosion prone environments with hot- dipped galvanizing or use stainless alloy. See UFC 1-200-01, section 4-1.3 for definition of corrosion prone environments. Coatings may be used alone in other environments. Select the appropriate system or material to suit the anticipated exposure. For exposed exterior steel deck and cold-formed steel members, provide ASTM A653/A653M G90 galvanizing and connect with corrosion-resistant fasteners. See Section A-5.4 of UFC 3-301-01 for additional guidance.

2-9.3 Section 2204 - COLD-FORMED STEEL.

2208.1 – Steel Roof Deck [Supplement]

Add the following to the end of the paragraph:

Steel roof deck is not permitted to be thinner than 22-gauge.

2-9.4 Section 2206 - COLD-FORMED STEEL LIGHT-FRAME CONSTRUCTION.

2206.1.1 - Seismic Requirements for Cold-Formed Steel Structural Systems [Replacement]

Design cold-formed steel light-frame construction to resist seismic forces in accordance with the provisions of Section 2206.1.1.1, and Section 2206.1.1.2 or Section 2206.1.1.3.

Renumber Sections 2206.1.1.1 and 2206.1.1.2 as 2206.1.1.2 and 2206.1.1.3, respectively.

2206.1.1.1 – Diagonal Bracing Material [Addition]

For diagonal bracing, use ASTM A653/A653M steel without rerolling.

[C] 2206.1.1.1 - Diagonal Bracing Material [Addition]

Rerolling induces strain hardening and reduces the elongation of the material and is therefore not desirable for performance under seismic loading.

2206.4 – Floor Vibrations [Addition]

Design cold-formed steel framing systems for vibration serviceability in accordance with the proposed design procedure in *Floor Vibration Design Criterion for Cold-Formed C-Shaped Supported Residential Floor Systems* by Kraus. The proposed design procedure is based on residential construction but is suitable for most applications of cold-formed steel floor construction.

2206.5 – Brick Veneer/Steel Stud Walls [Addition]

Follow the recommendations of BIA Technical Note 28B for the Design of steel stud backup for brick veneer. In particular, follow recommendations for minimum stud gage, minimum galvanization, minimum anchorage of studs to track, welding of studs, use of deflection track, allowable stud deflection, wall sheathing, and water-resistant barriers.

2206.6 – Cold-Formed Steel Connections [Addition]

Interconnect cold-formed steel members with screw fasteners or by welding. The use of pneumatic nailing is permitted only for the connection of cold-formed steel members to members made of other materials.

2206.7 – Galvanized Cold-Formed Framing [Addition]

Cold-formed steel members exposed to spray from salt, salt water, brackish water, or seawater must be galvanized with ASTM A653/A653M G90 galvanizing and all fasteners must be hot-dipped galvanized or made of stainless steel.

2-10 IBC CHAPTER 23 – WOOD.

2-10.1 Section 2308 – CONVENTIONAL LIGHT-FRAME CONSTRUCTION.

2308.2.6 – Risk category limitation [Replacement]

The use of the provisions for *conventional light-frame construction* in this section is not permitted for RC IV buildings assigned to *Seismic Design Category C, D, E, or F*, as determined per 2024 IBC Section 1613.2.

2-11 IBC CHAPTER 31 – SPECIAL CONSTRUCTION.

2-11.1 Section 3102 – MEMBRANE STRUCTURES.

3102.1 – Membrane Structures [Addition]

Structures with fabric envelopes or cladding, including but not limited to frame-supported, air-supported, cable net supported, grid shell supported, and geodesic dome supported are prohibited within windborne debris regions for Risk Categories II-V. Additionally, this prohibition applies where 1700-year-MRI wind speeds (IBC Figure 1609.3(2), ASCE 7 Figure 26.5-1C) equal or exceed wind speeds defining a windborne debris region, namely, 130 mph (58 m/s) within one mile of the coastal mean high-water line or 140 mph (63.6 m/s) anywhere else.

[C] 3102.1 – Membrane Structures [Addition]

Structures with fabric envelopes or cladding are prohibited for use in windborne debris regions due to the fabric's vulnerability to sharp flying debris. While a supporting frame may be designed to remain stable even with the loss of the fabric, risk to life and/or high value content remains. This prohibition is supported by lessons learned during recent hurricane and typhoon events.

Additionally, DoD also prohibits Structures with fabric envelopes or cladding for use in all locations where the 1700-year-MRI wind speed exceeds the threshold wind speed for windborne debris regions. This is because the risk of windborne debris damage is the same in these areas as in areas defined by the IBC as windborne debris regions. This additional requirement slightly expands IBC windborne debris regions.

This Page Intentionally Left Blank

CHAPTER 3 MODIFICATIONS TO ASCE 7

3-1 ASCE 7-22 CHAPTER 1 – GENERAL.

3-1.1 Section 1.3 - BASIC REQUIREMENTS.

1.3.1 – Strength and Stiffness [Supplement]

Add to the end of Item c.: During the design concept stage of development, documentation must be submitted to the AHJ for approval of the performance-based design approach.

1.3.1.3 – Performance-Based Procedures [Replacement]

Structural and nonstructural components and their connections must be demonstrated by a combination of analysis and testing to provide a reliability not less than that expected for similar components designed in accordance with the Strength Procedures of Section 1.3.1.1 when subject to the influence of dead, live, environmental, and other loads. Consideration must be given to uncertainties in loading and resistance.

1.3.1.3.3 – Documentation [Replacement]

Submit reports for approval to the AHJ and to an independent peer reviewer (where required), which document compliance with this section and the results of analysis and testing.

3-1.2 Section 1.5 - CLASSIFICATION OF BUILDINGS AND OTHER STRUCTURES.

Tables 1.5-1 and 1.5-2 [Replacement]

Replace Tables 1.5-1 and 1.5-2 of ASCE 7 with Table 2-2 of this UFC. All references in ASCE 7 to Tables 1.5-1 and 1.5-2 must be interpreted as a reference to Table 2-2 of this UFC. Items that are different from those in 2024 IBC Table 1604.5 are shown in italics.

3-2 ASCE 7-22 CHAPTER 2 – COMBINATIONS OF LOADS.

3-2.1 Section 2.3 - LOAD COMBINATIONS FOR STRENGTH DESIGN.

2.3.4 – Load Combinations Including Self-Straining Forces and Effects [Supplement]

Add to the end of the paragraph: The effect of load T needs to be taken into consideration on a structure. For further information see ASCE 7 Section C2.3.4.

[C] 2.3.4 - Load Combinations Including Self-Straining Forces and Effects [Supplement]

ASCE 7-22 Section 2.3.4 does not provide specific load factors to use with T . Commentary Section C.2.3.4 contains such load factors. The entire text of the commentary should be read and understood before using the load combinations in the commentary. The impact of T on serviceability and long-term performance of the facility may also need to be evaluated.

2.3.6 – Basic Combinations with Seismic Load Effects [Supplement]

Add before EXCEPTION: The following additional load combinations with seismic load effects must be considered for elements of buildings and nonbuilding structures specified in Section 1605.1.2 in Chapter 2 of this UFC. Provisions in the EXCEPTION that apply to combination 6 and 7 also apply to combinations 8 and 9, respectively.

Where the prescribed seismic load effect, $E = f(E_v, E_h)$, defined in ASCE 7 Section 12.4.2 or 12.14.3.1, is combined with the effects of other loads, the following seismic load combinations apply:

8. $1.2D + 1.0E_{v0} + 0.3E_h + L + 0.2S$

9. $0.9D - 1.0E_{v0} + 0.3E_h$

Where the seismic load effect with overstrength, $E_m = f(E_v, E_{mh})$, defined in ASCE 7 Section 12.4.3, is combined with the effects of other loads, the following seismic load combinations apply:

8. $1.2D + 1.0E_{v0} + 0.3E_{mh} + L + 0.2S$

9. $0.9D - 1.0E_{v0} + 0.3E_{mh}$

The effect of vertical ground motion, E_{v0} , can be determined from one of the following:

- $E_{v0} = 0.67S_{DS}D$
- E_{v0} is determined directly from the design vertical response spectrum given in ASCE 7 Section 11.9.

[C] 2.3.6 – Basic Combinations with Seismic Load Effects [Supplement]

The additional load combinations were derived using the 100+30 rule of combining the effects from orthogonal seismic loads. The code-specified vertical ground motion effect ($0.2S_{DS}D$) can be derived by first assuming peak vertical ground motion component to be $^{2/3}$ rd of the corresponding peak

horizontal component, and then combining 30% of that ($0.3 \times 0.67 S_{DS} = 0.2 S_{DS}$) with 100% of the horizontal seismic load effects. This section simply adds two more load combinations where 100% of the vertical seismic load effect is combined with 30% of the horizontal seismic load effect.

3-2.2 Section 2.4 – LOAD COMBINATIONS FOR ALLOWABLE STRESS DESIGN.

2.4.4 – Load Combinations Including Self-Straining Forces and Effects [Supplement]

Add to the end of the paragraph: The effect of load T needs to be taken into consideration on a structure. For further information, see ASCE 7 Section C2.4.4.

[C] 2.4.4 - Load Combinations Including Self-Straining Forces and Effects [Supplement]

ASCE 7-22 Section 2.4.4 does not provide specific load factors to use with T . Commentary Section C.2.4.4 contains such load factors. The entire text of the commentary should be read and understood before using the load combinations in the commentary. The impact of T on serviceability and long-term performance of the facility may also need to be evaluated.

2.4.5 – Basic Combinations with Seismic Load Effects [Supplement]

Add before EXCEPTIONS: The following additional load combinations with seismic load effects are to be considered for elements of buildings and nonbuilding structures specified in Section 1605.1.2 in Chapter 2 of this UFC. Provisions in the EXCEPTIONS that apply to combination 8, 9 and 10 also apply to combinations 11, 12 and 13, respectively.

Where the prescribed seismic load effect, $E = f(E_v, E_h)$, defined in ASCE 7 Section 12.4.2 or 12.14.3.1, is combined with the effects of other loads, the following seismic load combinations apply:

$$11. 1.0D + 0.7E_{v0} + 0.21E_h$$

$$12. 1.0D + 0.525E_{v0} + 0.1575E_h + 0.75L + 0.75S$$

$$13. 0.6D - 0.7E_{v0} + 0.21E_h$$

Where the seismic load effect with overstrength, $E_m = f(E_v, E_{mh})$, defined in ASCE 7 Section 12.4.3, is combined with the effects of other loads, the following seismic load combinations apply:

$$11. 1.0D + 0.7E_{v0} + 0.21E_{mh}$$

$$12. 1.0D + 0.525E_{v0} + 0.1575E_{mh} + 0.75L + 0.75S$$

$$13. 0.6D - 0.7E_{v0} + 0.21E_{mh}$$

The effect of vertical ground motion, E_{v0} , can be determined from one of the following:

- $E_{v0} = 0.67S_{DS}D$
- E_{v0} is determined directly from the design vertical response spectrum given in ASCE 7 Section 11.9.

[C] 2.4.5 – Basic Combinations with Seismic Load Effects [Supplement]

See the commentary to Section 2.3.6 above for some background on how the additional load combinations were derived.

3-2.3 Section 2.5 - LOAD COMBINATIONS FOR EXTRAORDINARY EVENTS.

2.5.1 – Applicability [Replacement]

When required, strength and stability must be checked to ensure that structures are capable of resisting the effects of progressive collapse according to UFC 4-023-03.

2.5.2 – Load Combinations [Deletion]

Delete this section in its entirety.

2.5.3 – Stability Requirements [Deletion]

Delete this section in its entirety.

3-3 ASCE 7-22 CHAPTER 6 – TSUNAMI LOADS.

3-3.1 Section 6.5 - ANALYSIS OF DESIGN INUNDATION DEPTH AND FLOW VELOCITY

6.5.3 – Sea Level Change [Supplement]

Subject to approval by the AHJ, a medium 2065 DoD Regional Sea Level Rise (DRSL) target may be utilized for Risk Category IV and V structures in tsunami prone regions when designing for a combination of tsunami and sea level rise. Design must incorporate future construction adaptation to either the High 2065 or Highest 2065 DRSL scenarios according to Table 2-2 for RC IV and V structures. Cost and risk must be considered when selecting adaptive design features. The adaptive design features must be included in the design analysis and in the design drawings and should be labeled, “Not in Contract (NIC)”, to permit future

construction as needed with negligible additional design cost or effort. The DRSL database is available at:

<https://sealevelscenarios.serdp-estcp.org>

3-3.2 Section 6.14 - TSUNAMI VERTICAL EVACUATION REFUGE STRUCTURES

6.14.1 - Minimum Inundation Elevation and Depth [Supplement]

Where a 1.3 factor is required, it is not cumulative to the Tsunami factor in Table 2-2, but rather supplants the tsunami factor in Table 2-2.

3-3.3 Section 6.15 - DESIGNATED NONSTRUCTURAL COMPONENTS AND SYSTEMS

6.15.1 – Performance Requirements [Supplement]

Design mission critical systems according to the requirements of Section 6.15.1. In addition to projected sea level rise (see Table 2-2), mission critical systems must be situated above maximum inundation elevation factored up by 1.3, unless designed directly for tsunami effects and if inundation would not inhibit critical function during and after a tsunami.

3-4 ASCE 7-22 CHAPTER 7 – SNOW LOADS.

3-4.1 Section 7.4 – Sloped Roof Snow Loads, p_s [Supplement].

Add to the end of the paragraph: Where obstructions occur on the roof from equipment such as photovoltaic panels, lightning cable systems, etc., the potential for snow buildup around the obstructions needs to be considered.

3-5 ASCE 7-22 CHAPTER 11 – SEISMIC DESIGN CRITERIA.

3-5.1 Section 11.1 – GENERAL.

11.1.2 – Scope [Supplement]

The design and detailing of the components of the seismic force-resisting system must comply with the applicable provisions of ASCE 7-22 Section 11.7 and ASCE 7-22 Chapter 12, as modified by this UFC, in addition to the nonseismic requirements of the 2024 IBC.

11.1.3 – Applicability [Supplement]

Add the following at the end of the section: Buildings or structures that are not routinely occupied, but whose primary purpose is to support human activities, such as training towers, are not to be classified as non-building structures unless specifically approved by the AHJ.

3-5.2 Section 11.2 – DEFINITIONS.

DESIGNATED SEISMIC SYSTEMS [Replacement]

The designated seismic system of a structure consists of those nonstructural components that require design in accordance with Chapter 13 and for which the component importance factor, I_p , is greater than 1.0. This designation applies to systems that are required to be operational following the design earthquake. Designated seismic systems will be identified by Owner and will have an importance factor, $I_p = 1.5$.

FRAME:

Moment Frame [Replacement]

A frame in which members and joints resist lateral forces by flexure as well as along the axis of the members. Moment frames are categorized as intermediate moment frames (IMF), ordinary moment frames (OMF), and special moment frames (SMF). Every joint must be restrained against rotation.

3-5.3 Section 11.5 - IMPORTANCE FACTOR AND RISK CATEGORY.

11.5.1 - Importance Factor [Replacement]

A seismic importance factor, I_e , must be assigned to each structure in accordance with Table 2-2 of this UFC.

3-6 ASCE 7-22 CHAPTER 12 – SEISMIC DESIGN REQUIREMENTS FOR BUILDING STRUCTURES.

3-6.1 Section 12.2 – STRUCTURAL SYSTEM SELECTION.

12.2.1 - Selection and Limitations [Supplement]

Table 3-1, Replacement for ASCE 7-22 Table 12.2-1, must be used in lieu of ASCE 7-22 Table 12.2-1.

3-6.2 Section 12.6 - ANALYSIS PROCEDURE SELECTION [Supplement].

Add at the end of the section:

For RC IV structures designed using the alternate procedure of Appendix B of this UFC, only nonlinear static or nonlinear response history procedure in accordance with the provisions of Appendix B is permitted.

FOR SI: 1 foot (ft) = 304.8 mm, 1 pound per square foot (psf) = 0.0479 kN/m²

- Response modification coefficient, R , for use throughout. Note R reduces forces to a strength level, not an allowable stress level.
- Where the tabulated value of the overstrength factor, Ω_o , is greater than or equal to 2½, Ω_o is permitted to be reduced by subtracting the value of ½ for structures with flexible diaphragms.
- Deflection amplification factor, C_d , for use in **ASCE 7-22** Sections 12.8.6, 12.8.7, 12.9.1.2, **12.12.2, 12.12.3, and 12.12.4.**

-
- d. NL= Not limited and NP = Not permitted. For metric units, use **30** m for 100 ft and **50** m for 160 ft.
 - e. See **ASCE 7-22** Section 12.2.5.4 for a description of seismic force-resisting systems limited to buildings with a structural height, h_n , of 240 feet (**75** m) or less.
 - f. See **ASCE 7-22** Section 12.2.5.4 for seismic force-resisting systems limited to buildings with a structural height, h_n , of 160 feet (**50** m) or less.
 - g. In Section 2.3 of ACI 318-19, a shear wall is defined as a structural wall.
 - h. In Section 2.3 of ACI 318-19, the definition of “special structural wall” includes precast and cast-in-place construction.
 - i. An increase in structural height, h_n , to 45 ft (**14** m) is permitted for single story storage warehouse facilities.
 - j. Steel ordinary concentrically braced frames (**OCBFs**) are permitted in single-story buildings up to a structural height, h_n , of 60 ft (**18** m) where the dead load of the roof does not exceed 20 psf (**1.0** kN/m²) and in penthouse structures.
 - k. See **ASCE 7-22** Section 12.2.5.7 for limitations in structures assigned to Seismic Design Categories D, E, or F.
 - l. See **ASCE 7-22** Section 12.2.5.6 for limitations in structures assigned to Seismic Design Categories D, E, or F.
 - m. In Section 2.3 of ACI 318-19, the definition of “special moment frame” includes precast and cast-in-place construction.
 - n. Cold-formed steel – special bolted moment frames must be limited to one-story in height in accordance with ANSI/AISI S400-20.
 - o. Alternately, the seismic load effect with overstrength, E_{mh} , is permitted to be based on the expected strength determined in accordance with ANSI/AISI S400-20.
 - p. Ordinary moment frame is permitted to be used in lieu of intermediate moment frame for Seismic Design Category B or C.
 - q. Structural height, h_n , shall not be less than 60 ft (18.3 m)
 - r. **Ordinary Moment Frames are permitted to be used as part of the structural system that transfers forces between isolator units.**
 - s. **ANSI/AISC 341-22 section number.**
 - t. **ACI 318-19, Section 18.2.1.6 cites appropriate sections in ACI 318-19.**
 - u. **TMS 402-22 section number.**
 - v. **2024 IBC section number.**
 - w. **2021 Special Design Provisions for Wind and Seismic with Commentary (SDPWS) section number.**

3-6.3 Section 12.10 - DIAPHRAGMS, CHORDS, AND COLLECTORS.

12.10.2.1 - Collector Elements Requiring Load Combinations with Overstrength Factor for Seismic Design Categories C through F

Item (c) [Replacement]. Forces calculated using the load combinations of Section 2.3.6 without overstrength factor, with seismic forces determined by Eq. (12.10-2).

EXCEPTION [Replacement]:

In structures or portions thereof braced entirely by wood light-frame shear walls, collector elements and their connections, including connections to vertical elements, need only be designed to resist forces using the load combinations of Section 2.3.6 without overstrength factor, with seismic forces determined in accordance with Section 12.10.1.1.

[C] 12.10.2.1 - Collector Elements Requiring Load Combinations with Overstrength Factor for Seismic Design Categories C through F

The two [Replacement] added under this section are intended to clarify that the load combinations to be used with these two provisions are the ones that do not include the overstrength factor. The text in ASCE 7-22 simply refers to the load combinations in Section 2.3.6. However, ASCE 7-22 Section 2.3.6 contains two sets of seismic load combinations – regular load combinations involving seismic load effects not amplified by the overstrength factor of the structure, and load combinations where the seismic load effects are amplified by the overstrength factor.

3-6.4 Section 12.11 - STRUCTURAL WALLS AND THEIR ANCHORAGE.

12.11.2.1 - Wall Anchorage Forces [Supplement]

Refer to Figure 3-1 for determination of the span of flexible diaphragm, L_f .

Figure 3-1 Anchorage of Walls to Flexible Diaphragm

3-7 ASCE 7-22 CHAPTER 13 – SEISMIC DESIGN REQUIREMENTS FOR NON-STRUCTURAL COMPONENTS.

3-7.1 Section 13.1 – GENERAL.

13.1.1 - Scope [Supplement]

Add as the last paragraph:

Appendix C of this UFC provides supplementary guidance on architectural, mechanical, and electrical component design requirements. Section C-2 provides guidance on architectural component design, including interior and exterior wall elements. Section C-3 provides guidance on electrical and mechanical systems design. To the extent that is practicable, subsections of Appendix C reference relevant sections of ASCE 7-22.

3-7.2 Section 13.2 - GENERAL DESIGN REQUIREMENTS.

13.2.3 - Special Certification Requirements for Designated Seismic Systems [Supplement]

Appendix D of this UFC provides verification and certification guidance.

When shake table testing is performed, the Required Response Spectra (RRS) must be either derived using ICC-ES AC156 or developed from a study based on site-specific in-structure response time history. In the case of the latter, the RRS for each axis must be generated from the time histories defined in Section 2-15.2

of UFC 3-301-02, and be peak broadened by 15%. The in-structure response spectra per Section 2-17.4.4 of UFC 3-301-02 must be used to determine demand if the Nonstructural Component is not supported at grade.

Testing must be performed in accordance with nationally recognized testing procedures such as:

1. The requirements of the International Code Council Evaluations Service (ICC-ES), *Acceptance Criteria for Seismic Qualification by Shake-Table Testing of Nonstructural Components*, ICC-ES AC156, November 2020.
2. The *CERL Equipment Fragility and Protection Procedure (CEFAPP)*, USACERL Technical Report 97/58, Wilcoski, J., Gambill, J.B., and Smith, S.J., March 1997. The test motions, test plan, and results of this method require peer review.
3. For power substation equipment only, Institute of Electrical and Electronics Engineers (IEEE), *Recommended Practices for Seismic Design of Substations*, IEEE 693-2018.

Shake table tests must include triaxial motion components that result in the largest response spectral amplitudes at the natural frequencies of the equipment for each of the three axes of motion. The Test Response Spectrum (TRS) test motions, demand RRS, test plan, and test results must be reviewed independently by a team of Registered Design Professionals. The design professionals must have documented experience in the appropriate disciplines, seismic analysis, and seismic testing. The independent review must include, but need not be limited to, the following:

1. Review of site-specific seismic criteria, including the development of site-specific spectra and ground motion histories, and all other project-specific criteria;
2. Review of seismic designs and analyses for both the equipment and all supporting systems, including the generation of in-structure motions;
3. Review of all testing requirements and results; and,
4. Review of all equipment quality control, quality assurance, maintenance, and inspection requirements.

13.2.3.1 - Component Certification and Operations & Maintenance (O&M) Manual [Addition]

For any electrical or mechanical component required by ASCE 7-22 Section 13.2.3 to be certified, evidence demonstrating compliance with the requirement must be maintained in a file identified as "Equipment Seismic Certification Documentation." This file must be a part of the Operations & Maintenance (O&M)

Manual that is turned over to the AHJ. The project specifications must require the O&M Manual to state that replaced or modified components need to be certified per the original certification criteria.

13.2.3.2 - Component Identification Nameplate [Addition]

Any electrical or mechanical component required by ASCE 7-22 Section 13.2.3 to be certified is required to bear permanent marking or nameplates constructed of a durable heat- and water-resistant material. Nameplates must be mechanically attached to such nonstructural components and placed on each component for clear identification. The nameplate cannot be less than 5 in. x 7 in. with red letters 1 in. in height on a white background, stating "Certified Equipment." The following statement is required to be on the nameplate: "This equipment/component is seismically certified. Modification or replacement must be approved in advance by a qualified professional engineer and documented in the "Equipment Seismic Certification Documentation" file within the O&M manuals. The nameplate needs to also contain the component identification number in accordance with the drawings/specifications and the O&M manuals.

3-7.3 Section 13.3 - SEISMIC DEMANDS ON NONSTRUCTURAL COMPONENTS.

13.3.2 - Seismic Relative Displacements [Supplement]

Egress stairways and ramps must be detailed in accordance with ASCE 7-22 Section 13.5.10.

3-7.4 Section 13.4 - NONSTRUCTURAL COMPONENT ANCHORAGE AND ATTACHMENT.

13.4.2.2 - Anchors in Masonry [Replacement]

Anchors in masonry must be designed in accordance with TMS 402-22. Additionally, at least one of the following must be satisfied in structures assigned to SDC C or higher.

- a. Anchors in tension are designed to be governed by the tensile strength of a ductile steel element.
- b. Anchors are designed for the maximum load that can be transmitted to the anchors from a ductile attachment, considering both material overstrength and strain hardening of the attachment.
- c. Anchors are designed for the maximum load that can be transmitted to the anchors by a non-yielding attachment.
- d. Anchors are designed for the maximum load obtained from design load combinations that include E , where the effect of horizontal ground motion, Q_E , is multiplied by Ω_{op} as given in ASCE 7-22 Tables 13.5-1 and 13.6-1.

[C] 13.4.2.2 - Anchors in Masonry [Replacement]

This [Replacement] harmonizes design of anchors embedded in concrete and masonry. ASCE 7-22 Section 13.4.2.2 includes provisions to prevent brittle failure of anchors in masonry attaching nonstructural components. This [Replacement] simply makes the requirements consistent with those of ACI 318-19. Note Option a is available only for anchors in tension, and not for those in shear. This [Replacement] also exempts anchors in SDC A and B structures from these ductility/overstrength requirements, which is consistent with what is required for anchors in concrete.

13.4.2.3 - Post-Installed Anchors in Concrete and Masonry [Replacement]

In structures assigned to SDC C or higher, post-installed mechanical anchors in concrete are required to be prequalified for seismic applications in accordance with ACI 355.2 or other approved qualification procedures. Post-installed adhesive anchors in concrete in structures assigned to SDC C, D, E, or F are required to be prequalified for seismic applications in accordance with ACI 355.4 or other approved qualification procedures. In structures assigned to SDC C or higher, post-installed anchors in masonry are required to be prequalified for seismic applications in accordance with approved qualification procedures.

[C] 13.4.2.3 - Post-Installed Anchors in Concrete and Masonry [Replacement]

This [Replacement] specifies that ACI 355.2 is for prequalification of post-installed mechanical anchors only and adds a reference to ACI 355.4 for prequalification of post-installed adhesive anchors, which is not referenced in ASCE 7-22.

3-7.5 Section 13.5 - ARCHITECTURAL COMPONENTS.

13.5.6 - Suspended Ceilings [Supplement]

For buildings assigned to RC IV, suspended ceilings must be designed to resist seismic effects using a rigid bracing system, where the braces are capable of resisting tension and compression forces, or diagonal splay wires, where the wires are installed taut. Particular attention should be paid in walk-down inspections (see Section 1705.13.6 in Chapter 2 of this UFC) to ensure splay wires are taut. Positive attachment must be provided to prevent vertical movement of ceiling elements. Vertical support elements need to be capable of resisting both compressive and tensile forces. Vertical supports and braces designed for compression must have a slenderness ratio, Kl/r , of less than 200. Additional guidance on suspended ceiling design is provided in Section C-2.2.8 of this UFC.

13.5.7 – Access Floors [Supplement]

Installed access floor components that have importance factors, I_p , greater than 1.0 must meet the requirements of Special Access Floors (ASCE 7-22 Section 13.5.7.2). Note: Equipment that requires certification (see Section 13.2.3 in this UFC) needs to account for the motion amplification that occurs because of any supporting access flooring.

3-7.6 Section 13.6 - MECHANICAL AND ELECTRICAL COMPONENTS.

13.6.1 - General [Supplement]

Stacks attached to or supported by buildings must be designed to meet the force and displacement provisions of ASCE 7-22 Sections 13.3.1 and 13.3.2. They must further be designed in accordance with the requirements of ASCE 7-22 Chapter 15 and the special requirements of ASCE 7-22 Section 15.6.2. Guidance on stack design may be found in Section C-3.2.

13.6.2 - Mechanical Components [Supplement]

Guidance on the design of piping supports and attachments is found in Section C-3.1.3 of this UFC.

13.6.3 - Electrical Components [Supplement]

Guidance on the design of electrical equipment supports, attachments, and certification is found in Appendices C and D of this UFC.

13.6.4 - Component Support [Supplement]

For buildings that are assigned to RC IV, guidance on the design of lighting fixtures is found in Section C-3.4 of this UFC.

13.6.11.3 - Seismic Controls for Elevators [Supplement]

For buildings that are assigned to RC IV or to SDC E or F, the trigger level for seismic switches must be set to 50% of the acceleration of gravity along both orthogonal horizontal axes. Elevator systems (equipment, supports, etc.) in RC IV or SDC E or F buildings will have an $I_p = 1.5$ and must be designed to ensure elevator operability at accelerations below 50% of the acceleration of gravity along both orthogonal horizontal axes. Additional guidance on the design of elevator systems is found in Section C-3.3 of this UFC.

[C] 13.6.11.3 - Seismic Switches [Supplement]

Note that the 0.50g is consistent with Article 3137, *Seismic Requirements for Elevators, Escalators and Moving Walks*, Subchapter 6, Elevator Safety Orders, California Code of Regulations, Title 8 (<https://www.dir.ca.gov/title8/3137.html>).

13.6.12 - Rooftop Solar Panels [Deletion]

Delete the exception to this section in its entirety.

[C] 13.6.12 - Rooftop Solar Panels [Deletion]

The exception addresses ballasted solar panels without positive direct attachment to the roof structure. Ballasted systems are specifically disallowed by UFC 3-110-03, *Roofing*.

13.6.14 - Bridges, Cranes, and Monorails [Addition]

Structural supports for those crane systems that are located in buildings and other structures assigned to SDC C with I_p greater than 1.0, or assigned to SDC D, E, or F, must be designed to meet the force and displacement provisions of ASCE 7-22 Section 13.3. Seismic forces, F_p , must be calculated using $C_{AR}/R_{po} = 1$, except that crane rail connections must be designed for the forces resulting from $C_{AR}/R_{po} = 1.15$ in all directions. When designing for forces in either horizontal direction, the weight of crane components, W_p , need not include any live loads, lifted loads, or loads from crane components below the bottom of the crane cable. If the crane is not in a locked position, the lateral force parallel to the crane rails can be limited by the friction forces that can be applied through the brake wheels to the rails. In this case, the full rated live load of the crane plus the weight of the crane must be used to determine the gravity load that is carried by each wheel. Guidance on the design of these systems is found in Section C-3.5 of this UFC.

[C] 13.6.14 - Bridges, Cranes, and Monorails [Addition]

The parameters a_p and R_p are not used in ASCE 7-22. However, there is no direct correspondence between these and the new parameters in ASCE 7-22: the Component Resonance Ductility Factor, C_{AR} , and the Component Strength Factor, R_{po} . The ratio $C_{AR}/R_{po} = 1.0$ preserves the previous $a_p/R_p = 1.0$.

Since crane rail connections are not listed in Table 13.6-1, R_{po} for those connections is taken as 1.3 which is the lowest R_{po} value in the entire Table 13.6-1. Cranes and Monorails fall under Other mechanical components and are assigned an R_{po} of 1.5. Thus, C_{AR}/R_{po} ratio is raised by a factor of $1.5/1.3 = 1.15$.

13.6.14.1 - Bridges, Cranes, and Monorails for RC IV Buildings [Addition]

In addition to the requirements of Section 13.6.14 of this UFC, for bridges, cranes, and monorails for all RC IV buildings, vertical earthquake-induced motions corresponding to the MCE_R event must be considered. When a site-specific vertical spectrum is not used, the vertical response spectrum may be developed following the provisions of ASCE 7-22 Section 11.9.2.

3-8 ASCE 7 CHAPTER 15 – SEISMIC DESIGN REQUIREMENTS FOR NONBUILDING STRUCTURES.

3-8.1 Section 15.4 - STRUCTURAL DESIGN REQUIREMENTS.

15.4.5 – Drift Limit [Replacement]

Nonbuilding structures similar to buildings are required to comply with lateral drift limitations specified for buildings in ASCE 7-22 Chapter 12.

EXCEPTION: The drift limitations of ASCE 7-22 Section 12.12.1 need not apply to nonbuilding structures if a rational analysis acceptable to the AHJ indicates they can be exceeded without adversely affecting structural stability of attached or interconnected components and elements such as walkways and piping. P -delta effects need to be considered where critical to the function or stability of the structure.

15.4.9.2 - Anchors in Masonry [Replacement]

Anchors in masonry must be designed in accordance with TMS 402-22. Additionally, for non-building structures assigned to SDC C, D, E, or F, at least one of the following must be satisfied.

- a. Anchors in tension are designed to be governed by the tensile strength of a ductile steel element.
- b. Anchors are designed for the maximum load that can be transmitted to the anchors from a ductile attachment, considering both material overstrength and strain hardening of the attachment.
- c. Anchors are designed for the maximum load that can be transmitted to the anchors by a non-yielding attachment.
- d. Anchors are designed for the maximum load obtained from design load combinations that include E , where the effect of horizontal ground motion, Q_E , is multiplied by Ω_o as given in ASCE 7-22 Tables 13.5-1 and 13.6-1.

[C] 15.4.9.2 - Anchors in Masonry [Replacement]

This [Replacement] harmonizes design of anchors embedded in concrete and masonry. ASCE 7-22 Section 15.4.9.2 includes provisions to prevent brittle failure of anchors in masonry in nonbuilding structures. This [Replacement] simply makes the requirements consistent with those of ACI 318-19. Note Option 'a' is available only for anchors in tension, not shear.

15.4.9.3 - Post-Installed Anchors in Concrete and Masonry [Replacement]

Post-installed mechanical anchors in concrete in non-building structures assigned to SDC C, D, E, or F are required to be prequalified for seismic applications in accordance with ACI 355.2 or other approved qualification procedures. Post-installed adhesive anchors in concrete in non-building structures assigned to SDC C, D, E, or F are required to be prequalified for seismic applications in accordance with ACI 355.4 or other approved qualification procedures. Post-installed anchors in masonry non-building structures assigned to SDC C, D, E, or F are required to be prequalified for seismic applications in accordance with approved qualification procedures.

[C] 15.4.9.3 - Post-Installed Anchors in Concrete and Masonry [Replacement]

This [Replacement] specifies that ACI 355.2 is for prequalification of post-installed mechanical anchors only and adds a reference to ACI 355.4 for prequalification of post-installed adhesive anchors, which is not referenced in ASCE 7-22.

3-8.2 Section 15.5 - NONBUILDING STRUCTURES SIMILAR TO BUILDINGS.

15.5.6.1 - General [Supplement]

UFC 4-152-01, *Design: Piers and Wharves*, governs the seismic design of piers and wharves for the DoD.

15.5.6.2 - Design Basis [Deletion]

Delete this section in its entirety.

3-8.3 Section 15.7 - TANKS AND VESSELS.

15.7.5 – Anchorage

Item (c) [Replacement]

Post-installed anchors are permitted to be used in accordance with Section 15.4.9.3 of this UFC, provided the anchor embedment into the concrete is sufficient to develop the steel strength of the anchor rod in tension.

15.7.11.7 – Supports and Attachments for Boilers and Pressure Vessels

Item (b) [Replacement]

Anchorage must be in accordance with Chapter 17 of ACI 318. Post-installed anchors are permitted to be used in accordance with Section 15.4.9.3 of this UFC, provided the anchor embedment into the concrete is sufficient to develop the steel strength of the anchor rod in tension. For anchors in tension, where the special seismic provisions of ACI 318 Section 17.10.5.2 apply, the requirements of ACI 318 Section 17.10.5.3(a) must be satisfied.

3-9 ASCE 7 CHAPTER 26 – WIND LOADS: GENERAL REQUIREMENTS.

3-9.1 Section 26.12 - ENCLOSURE CLASSIFICATION.

26.12.1 - General. [Supplement]

Design all fire station garage bays as partially enclosed structures, with the assumption that garage bay doors have failed. The remainder of the fire station, if isolated from garage bay internal pressure, may be designed according to standard code provisions.

[C] 26.12.1 - General [Supplement]

Damage experienced during Hurricane Michael in 2018 included multiple instances of roof diaphragm loss due to exterior roll-up and sectional door failures, including a fire station where bay doors failed, followed by a total loss of roof diaphragm.

This Page Intentionally Left Blank

CHAPTER 4 EVALUATION AND RETROFIT OF EXISTING BUILDINGS

4-1 GENERAL.

For evaluation and retrofit of existing buildings, the provisions of this chapter apply to all matters governing the *repair, alteration*, change of occupancy, acquisition, *addition*, and relocation. For seismic evaluation and retrofit, the following document is hereby adopted:

ICSSC RP 10, *Standards of Seismic Safety for Existing Federally Owned and Leased Buildings*, cited herein as RP 10, is applicable to all existing DoD owned and leased buildings at all locations worldwide.

For nonseismic evaluation and retrofit of existing buildings relating to all matters governing the *repair, alteration*, change of occupancy, acquisition, *addition*, and relocation, the following document is hereby adopted:

International Code Council, *2024 International Existing Building Codes*, cited herein as IEBC.

Modifications are made to specific sections of RP 10 as well as IEBC. It is expected that designers may highlight or otherwise mark those paragraphs of RP 10, and IEBC that are modified by this chapter. The required RP 10, and IEBC section modifications are one of three actions, according to the following legend:

[Addition] – New section added, includes new section number not shown in RP 10 or the 2024 IEBC.

[Replacement] – Delete referenced RP 10 or 2024 IEBC section and replace it with the provisions shown.

[Supplement] – Add provisions shown as a supplement to the provisions shown in the referenced section of RP 10 or the 2024 IEBC.

[C] 4-1 General

RP 10, *Standards of Seismic Safety for Existing Federally Owned and Leased Buildings*, gives exemptions, triggers, scope, and criteria applicable to repair, alteration, change of occupancy, acquisition, addition to and relocation of existing buildings. RP 10 uses the national standard ASCE 41-17 as the source of its criteria for seismic evaluation and retrofit.

This Chapter clarifies certain terms used in RP 10 and the application of RP 10 to various risk categories. RP 10's exemptions and benchmarking provisions are also modified by this chapter.

The IEBC, *International Existing Building Code*, establishes minimum requirements for existing buildings using prescriptive and performance-related provisions. It is

founded on broad-based principles intended to encourage the use and reuse of existing buildings while requiring reasonable updates and improvements.

This Chapter contains modifications to the 2024 IEBC including the scope, and the prescriptive compliance method for nonseismic evaluation of existing buildings.

4-2 MODIFICATIONS TO RP 10.

Apply the following modifications to RP 10.

4-2.1 Circumstances Initiating Evaluation and Mitigation (Triggers).

RP10 Section 1.0 [Supplement]. Wherever RP10 cites 2021 IBC and 2021 IEBC, the corresponding section or provision of 2024 IBC and 2024 IEBC is to be used instead. Wherever RP10 cites ASCE 7-16, the corresponding section or provision of ASCE 7-22 is to be used instead.

RP 10 Section 1.2.1 Item c [Replacement]. An *addition, alteration, or repair* to a building assigned to Seismic Design Category (SDC) C, where the project construction cost is more than 50 percent of the current pre-construction replacement cost of the building (not including tenant supplied operational service equipment and fit-outs or seismic mitigation efforts).

RP 10 Section 1.2.1 Item d [Replacement]. An *addition, alteration, or repair* to a building assigned to Seismic Design Category (SDC) D, E or F, where the project construction cost is more than 30 percent of the current pre-construction replacement cost of the building (not including tenant supplied operational service equipment and fit-outs or seismic mitigation efforts).

4-2.2 Performance Objectives for Evaluation and Retrofit using ASCE 41-17.

RP 10 Section 2.0 [Supplement]. Tables 4-1(a) and 4-1(b) of this chapter must be used for structural and nonstructural components, respectively, in lieu of RP 10 Tables 2-1, 2-2, and 2-3 for determining the required performance objectives for evaluation and retrofit based on the risk category of building and the circumstance that triggered the requirement for evaluation and retrofit. At the AHJ's discretion, the nonstructural scope may be waived in areas of the building not affected by the project and not affecting DoD operations, safety, or post-earthquake occupancy.

[C] RP 10 Section 2.0 [Supplement]. Tables 4-1(a) and 4-1(b) do not revise the requirements contained in RP 10 Tables 2-1, 2-2 and 2-3, but are meant to present the same requirements with more clarity. One exception is Item i in Table 4-1(a), Unacceptable Risk Exposure (URE) trigger, where RP 10 does not provide any clear evaluation criteria but leaves it to the discretion of each agency to decide which buildings they choose to assign to the URE designation. However, NIST wanted agencies to be more proactive about

retrofitting at least their URMs and similar buildings. Thus, Item i in Table 4-1(a) was developed with a focus on URMs. A fairly low threshold of Collapse Prevention in BSE-1E is used for the evaluation of these buildings in all risk categories, because these buildings are not expected to pass any higher evaluation threshold. The retrofit requirements are the same as those for other project types that require basic performance objective for existing buildings (BPOE). If attaining the retrofit performance objectives becomes a challenge for URM buildings in higher risk categories, an effective solution would be to relocate the activities housed in those buildings.

RP10 Section 2.1 [Supplement]. For definition of enhanced performance objective greater than that specified in Table 2-1 in RP10, refer to ASCE 41-17 Section 2.2.2.

Seismic multi-period response spectra for BSE-1E, BSE-2E, BSE-1N, and BSE-2N earthquakes at DoD installations within the United States and its territories and possessions can be determined using the ASCE Hazard Tool (<https://ascehazardtool.org/>).

For locations not included in the ASCE Hazard Tool, consult the AHJ.

[C] RP10 Section 2.1 [Supplement]. RP 10 references four seismic hazard levels – BSE-2N (2% probability of exceedance in 50 years), BSE-1N ($2/3$ of BSE-2N), BSE-2E (5% probability of exceedance in 50 years) and BSE-1E (20% probability of exceedance in 50 years). The ASCE Hazard Tool (<https://ascehazardtool.org/>) provides seismic multi-period response spectra for all four hazard levels for any location within the conterminous United States.

¹ CP = Collapse Prevention; LmS = Limited Safety; LS = Life Safety; DC = Damage Control; IO = Immediate Occupancy

² See [C] RP10 Section 2.1 [Supplement] of this UFC for definitions of BSE-1E, BSE-2E, BSE-1N, and BSE-2N

³ At the AHJ's discretion, Tier 3 evaluation at BSE-1 hazard level may also be required, for performance levels required for corresponding retrofit.

⁴ For Risk Category III, Tier 1 screening or Tier 2 evaluation at the Limited Safety level are to use the Tier 1 checklists and Tier 2 procedures for Collapse Prevention performance, but M_s -factors and other quantitative limits are to be taken as the average of Life Safety and Collapse Prevention values.

⁵ For Risk Category IV, Tier 1 screening or Tier 2 evaluation at the Life Safety level are to use the Tier 1 checklists and Tier 2 procedures for Collapse Prevention performance, but M_s -factors and other quantitative limits are to be taken as Life Safety values.

¹ LS = Life Safety; PR = Position Retention; OP = Operational; HR = Hazard Reduced

² See [C] RP10 Section 2.1 [Supplement] of this UFC for definitions of BSE-1E, BSE-2E, BSE-1N, and BSE-2N

³ If initial evaluation indicates that damage to nonstructural components would pose an unacceptable risk exposure to the occupants or to the agency's mission, the agency may supplement the initial scope with evaluation considering the 'LS' performance level at the BSE-2E or BSE-2N seismic hazard level

⁴ For buildings assigned to Risk Category I or II, a nonstructural component need only be evaluated for the 'LS' performance level if evaluation for the 'PR' performance level would, in the judgment of the federal agency, disproportionately affect project feasibility.

4-2.3 Exemptions and Benchmark Buildings.

4-2.3.1 Exemptions.

Where applied to projects involving change of occupancy, exemptions in RP 10 Section 1.3 based on occupancy or use apply to the new or intended occupancy.

RP 10 Section 1.3, Item e [Replacement]. Risk Category I or II building structures intended for incidental human occupancy not exceeding two persons per 100 ft² of space for a total of less than 2 hours a day.

4-2.3.2 Benchmark Buildings.

RP 10 Section 1.4 [Supplement]. Where the Benchmark Building provisions of ASCE 41-17 apply, Table 4-2 of this chapter is to replace ASCE 41-17 Table 3-2, Benchmark Building Codes and Standards for Life Safety Structural Performance at BSE-1E and Table 3-3, Benchmark Building Codes and Standards for Immediate Occupancy Structural Performance at BSE-1E.

4-3 ADDITIONAL REQUIREMENTS.

4-3.1 Combined Projects.

Alteration work performed in conjunction with an addition project must comply with the provisions for alteration projects. Repair work performed in conjunction with an addition project must comply with the provisions for repair projects.

[C] 4-3.1 Combined Projects

In general, RP 10 makes provisions based on the intended project type. This added section addresses cases where multiple project types, one of which is an addition, are undertaken. The provision is primarily a pointer to the requirements in this chapter.

4-3.2 Existing Structural Elements Carrying Lateral Load.

Where an addition is structurally independent of the existing structure, existing seismic force-resisting structural elements are permitted to remain unaltered. Where the addition is not structurally independent of the existing structure, the existing structure and its *addition* acting together as a single structure must be shown to meet the requirements of 2024 IBC Sections 1609 and 1613. For the purposes of this section, compliance with ASCE 41-17, using a Tier 3 procedure and the retrofit performance objective given in Table 4-1(a) of this chapter is to be deemed to meet the requirements of Section 1613.

Exception: Any existing seismic force-resisting structural element whose demand-capacity ratio with the addition considered is no more than 10 percent

greater than its demand-capacity ratio with the addition ignored is permitted to remain unaltered provided the addition neither creates new structural irregularities, as defined in ASCE 7-22 Section 12.3.2, nor makes existing structural irregularities more severe. For purposes of calculating demand-capacity ratios, the demand must consider applicable load combinations that include wind or earthquake load effects. For purposes of this exception, comparisons of demand-capacity ratios and calculation of design lateral loads, forces and capacities must account for the cumulative effects of additions and alterations since original construction.

4-3.2.1 Alterations

If no alterations are made to an existing structure that receives a new structurally independent addition, then seismic evaluation of the existing structure is not required. If alterations are made to an existing structure that receives a new structurally independent addition, the requirements of RP 10 must be met for the existing structure.

4-3.2.2 Repairs

If no repairs are made to an existing structure that receives a new structurally independent addition, then seismic evaluation of the existing structure is not required. If repairs are made to an existing structure that receives a new structurally independent addition, the requirements of RP 10 must be met for the existing structure.

Table 4-2 Replacement for ASCE/SEI 41-17 Tables 3-2 and 3-3 for Benchmark Buildings

^{LS} Only buildings designed and constructed or evaluated in accordance with these documents and being evaluated to the Life-Safety Performance Level may be considered Benchmark Buildings.

^{IO} Buildings designed and constructed or evaluated in accordance with these documents and being evaluated to the Immediate Occupancy Performance Level may be considered Benchmark Buildings.

NBM - No benchmark year; buildings need to be evaluated.

NP – Not Permitted. Tri-Services guidance does not permit the use of URM.

¹ Building Type refers to one of the Common Building Types defined in **ASCE 41-17** Table 3-1.

² Buildings on hillside sites must not be considered Benchmark Buildings.

³ For buildings in areas of Very Low Seismicity, the benchmark provisions are to be limited to the IBC, FEMA 310/ASCE 31, and FEMA 356/ASCE 41.

⁴ Life Safety Structural Performance Level for the seismic hazard as defined by those provisions.

⁵ Immediate Occupancy Structural Performance Level for the seismic hazard as defined by those provisions.

⁶ Life Safety Structural Performance Level for BSE-1 seismic hazard as defined by those provisions.

⁷ Immediate Occupancy Structural Performance Level for BSE-1 seismic hazard as defined by those provisions.

⁸ ***The Tri-Services Criteria Benchmark Year provisions apply only to the structural aspects of the evaluation; older retrofits designed using Tri-Services Criteria need to be evaluated for compliance with the new standards. Nonstructural and foundation elements are required to have a minimum Tier 1 evaluation, in accordance with ASCE 41-17, except under the following circumstances:***

a. The building was designed and constructed in accordance with TI 809-04 or later Tri-Services criteria; or,

b. The building was evaluated in accordance with TI 809-05 or later Tri-Services criteria, and the building evaluation and rehabilitation included structural, nonstructural, geotechnical, and foundation measures.

⁹ Steel moment-resisting frames and eccentrically braced frames with links adjacent to columns must comply with the 1994 UBC Emergency Provisions, published September/October 1994, or subsequent requirements.

¹⁰ ***Pre-engineered metal buildings designed in accordance with 1992 criteria using ASCE 7 loading may be considered as Benchmark Buildings for Life Safety Performance Objective, only if all other applicable restrictions are met. Pre-engineered metal buildings designed in accordance with 1998 criteria, including TI 809-30, Metal Building Systems, may be considered as Benchmark Buildings for both the Life Safety and Immediate Occupancy Performance Objectives, only if all other applicable restrictions are met.***

¹¹ Cold-formed steel shear walls with wood structural panels only.

¹² Flat slab concrete moment frames must not be considered Benchmark Buildings.

¹³ ***This benchmark year is based in the initial publication of TI 809-07, Design of Cold-Formed Load-Bearing Steel System and Masonry Veneer Steel Stud Walls, 1998.***

NBC – Building Code Officials and Code Administrators International (BOCA), *National Building Code*, 1993.

SBC – Southern Building Code Congress International (SBCC), *Standard Building Code*, 1994.

UBC – International Conference of Building Officials (ICBO), *Uniform Building Code*, ***year as shown in table.***

1982 – TM 5-809-10; NAVFAC P-355; AFM 88-3, Ch 13, Seismic Design for Buildings, 1982.

1986 – TM 5-809-10-1; NAVFAC P-355.1; AFM 88-3, Ch 13, Sec A, Seismic Design Guidelines for Essential Buildings, 1986.

1988 – TM 5-809-10-2; NAVFAC P-355.2; AFM 88-3, Ch 13, Sec B, Seismic Design Guidelines for Upgrading Existing Buildings, 1988.

1992 – TM 5-809-10; NAVFAC P-355; AFM 88-3, Ch 13, Seismic Design for Buildings, 1992.

4-4 MODIFICATIONS TO IEBC.

4-4.1 IEBC Part 1 – scope and application.

101.2 – Scope [Supplement]

ASCE 7-22 Chapter 6, Tsunami Loads and Effects, does not apply to Repairs, Alterations, and Changes of Occupancy of Existing Buildings and Other Structures as defined by the 2024 International Existing Building Code (IEBC).

[C] 101.2 - Scope [Supplement]

The IEBC does not currently incorporate Tsunami requirements. Accordingly, this [Supplement] is provided as clarification. This may change with future editions of the IEBC.

4-4.2 IEBC Chapter 5 – prescriptive compliance method.

503.12 – Roof Diaphragms Resisting Wind Loads in High-wind Regions [Replacement]

When a building alteration or repair is performed where the basic wind speed for RC II structures is greater than 130 mph (58 m/s) or where it is a special wind region in accordance with this UFC, roof diaphragms, diaphragm connections to roof framing members, and diaphragm-to-wall connections must be evaluated for wind loads specified in this UFC, provided at least one of the following conditions occurs and this provision has not been invoked in the previous 25 years:

1. The cost of the alteration or repair exceeds 50% of replacement value for the building.
2. Reroofing a Risk Category III or IV building involves removal of more than 50 percent of roofing material.

If the diaphragm and/or diaphragm connections are found incapable of resisting 75 percent of the current UFC design wind loads, they must be replaced or strengthened in accordance with current design wind loads specified in this UFC.

Exception: The following building types are exempt from this requirement:

- Reinforced concrete buildings with concrete diaphragms
- Reinforced concrete masonry unit buildings with concrete diaphragms.
- Detached one- and two-family dwellings
- Multiple single-family dwellings (townhouses) with less than eight attached dwelling units not more than three stories above grade.

- Risk Category I buildings

[C] 503.12 – Roof Diaphragms Resisting Wind Loads in High-wind Regions [Replacement]

High-Wind regions are defined in the 2024 IEBC as areas where the basic wind speed equals or exceeds 130 mph (58 m/s).

4-4.3 IEBC Chapter 7 – alterations - level one.

706.3.2 - Roof Diaphragms Resisting Wind Loads in High-wind Regions [Replacement]

Apply section 503.12 of this UFC.

CHAPTER 5 NONBUILDING STRUCTURES

5-1 HIGHWAY BRIDGE DESIGN.

Design of highway bridges is required to be in accordance with *AASHTO* LRFD Bridge Design Specifications. Design examples are available in the PCI Bridge Design Manual and the following links

- *LRFD Design Examples* (<https://www.fhwa.dot.gov/bridge/lrfd/examples.cfm>)
- *Reference Manual* (<https://www.fhwa.dot.gov/bridge/pubs/nhi15047.pdf>)

5-2 RAILROAD BRIDGE DESIGN.

Design of railroad bridges is required to be in accordance with the AREMA Manual for Railway Engineering.

5-3 TANKS FOR LIQUID STORAGE.

Design of tanks for liquid storage is required to be in accordance with NFPA 22, AWWA D100, AWWA D103, AWWA D107, AWWA D115, AWWA D110 and AWWA D120 as applicable.

5-4 TANKS FOR PETROLEUM STORAGE.

Design of tanks for petroleum storage is required to be in accordance with UFC 3-460-01.

5-5 ENVIRONMENTAL ENGINEERING CONCRETE STRUCTURES.

Design of environmental engineering concrete structures is required to be in accordance with ACI CODE-350.

5-6 PRESTRESSED CONCRETE TANKS.

Design of prestressed concrete tanks is required to be in accordance with ACI 372R.

5-7 WATER TREATMENT FACILITIES.

Design of water treatment facilities is required to be in accordance with the Water Environment Federation (WEF) Manual of Practice (MOP) 8.

5-8 TRANSMISSION TOWERS AND POLES.

Design of transmission towers is required to be in accordance with ASCE 10. Design of transmission poles is required to be in accordance with IEEE Standards Association's National Electric Safety Code.

5-9 ANTENNA TOWERS.

Design of antenna towers is required to be in accordance with ANSI/TIA-222-H.

5-10 PEDESTRIAN BRIDGES.

Design of pedestrian bridges is required to be in accordance with the AASHTO LRFD Guide Specifications for Design of Pedestrian Bridges.

CHAPTER 6 MODIFICATIONS TO THE IBC FOR CRITICAL HEALTHCARE FACILITIES

This Chapter adopts some of the modifications made by the 'A' chapters of the 2022 California Building Code for DoD's critical healthcare facilities. The 2022 CBC is based on the 2021 IBC. The 2025 CBC, based on the 2024 IBC, was not available when this Chapter was finalized. So, any reference to IBC in this Chapter is to the 2021 IBC and its referenced standards: ASCE 7-16, ACI 318-19, TMS 402-16, AISC 360-16, and AISC 341-16. This Chapter will need to be updated once the 2025 CBC is published.

6-1 IBC CHAPTER 1 – SCOPE AND ADMINISTRATION.

6-1.1 Section 101 – GENERAL.

101.2 – Scope. [Supplement]

For the seismic design of the facilities listed below assigned to SDC D, E, or F, the modifications to 2021 IBC Chapters 16, 18, 19, 21, and 22 included in this chapter apply in addition to those in Chapter 2 of this UFC. Where the provisions of this chapter and those in the 2021 IBC or in Chapter 2 of this UFC are in conflict, the provisions of this chapter govern.

- Group I-2, Condition 2 occupancies, as defined in 2021 IBC Section 308.3, having emergency surgery or emergency treatment facilities.
- Ambulatory care facilities having emergency surgery or emergency treatment facilities.

6-2 IBC CHAPTER 16 – STRUCTURAL DESIGN.

6-2.1 Section 1603 – CONSTRUCTION DOCUMENTS.

1603.1.5 – Earthquake Design Data. [Supplement]

Add the following three items to the list:

12. Applicable horizontal structural irregularities.
13. Applicable vertical structural irregularities.
14. Location of base as defined in ASCE 7-16 Section 11.2.

6-3 IBC CHAPTER 18 – SOILS AND FOUNDATIONS.

6-3.1 Section 1807 – FOUNDATION WALLS, RETAINING WALLS AND EMBEDDED POSTS AND POLES.

1807.1.1 – Design Lateral Soil Loads. [Replacement]

Foundation walls must be designed for the lateral soil loads determined by a geotechnical investigation, in accordance with Section 1803.

1807.1.3 – Rubble Stone Foundation Walls. [Replacement]

Rubble stone foundation walls are not permitted.

1807.1.4 – Permanent Wood Foundation Systems. [Replacement]

Permanent wood foundation systems are not permitted.

1807.2.2 – Design Lateral Soil Loads [Replacement]

Retaining walls shall be designed for the lateral soil loads determined by a geotechnical investigation in accordance with Section 1803 and shall not be less than eighty percent of the lateral soil loads determined in accordance with Section 1610. For use with the load combinations, lateral soil loads due to gravity loads surcharge shall be considered gravity loads and seismic earth pressure increases due to earthquake shall be considered as seismic loads. For structures assigned to Seismic Design Category D, E, or F, the design of retaining walls supporting more than 6 feet (1829 mm) of backfill height shall incorporate the additional seismic lateral earth pressure in accordance with the geotechnical investigation where required in Section 1803.2.

6-4 IBC CHAPTER 19 – CONCRETE.

6-4.1 Section 1901 – GENERAL.

1901.5 – Construction Documents [Supplement]

Add the following item to the list:

12. Detailing of openings larger than 12 inches (305 mm) in any dimension.

6-4.2 Section 1903 – SPECIFICATIONS FOR TESTS AND MATERIALS.

1903.4 – Flat Wall Insulating Concrete Form (ICF) Systems. [Replacement]

Insulating concrete form material used for forming flat concrete walls shall not be permitted for hospitals or correctional treatment centers; they shall conform to ASTM E2634 for skilled nursing and intermediate care facilities and clinics.

**1903.5 – Aggregates – Modify ACI 318 Section 26.4.1.2.1(a).(1) as follows:
[Addition]**

(1) Normal weight aggregate: Aggregate shall be nonreactive as determined by one of the methods in ASTM C33 Appendix XI: Methods for Evaluating Potential

for Deleterious Expansion Due to Alkali Reactivity of an Aggregate. Aggregates deemed to be deleterious or potentially deleterious may be used with the addition of a material that has been shown to prevent harmful expansion in accordance with Appendix XI of ASTM C33, when approved by the Authority Having Jurisdiction.

1903.6 – Limits on Cementitious Materials. [Addition]

For hospitals and correctional treatment centers, modify ACI 318 Section 26.4.2.2(b) as follows:

The maximum percentage of pozzolans, including fly ash and silica fume, and slag cement in concrete assigned to all exposure categories shall be in accordance with Table 26.4.2.2(b) and Section 26.4.2.2(b) Items (1) and (2).

Where pozzolans are used as cementitious materials, duration for minimum specified compressive strength of concrete (f'_c) that exceeds 28 days shall be considered an alternative system.

1903.7 – Steel Fiber Reinforcement [Addition]

Steel fiber reinforcement is not permitted.

6-4.3 Section 1905 – MODIFICATIONS TO ACI 318.

Retain Section 1905.1.8, renumbered as 1905.1.4, and replace the other modifications to ACI 318-19 made in the 2021 IBC Section 1905 with the following modifications.

1905.1.1 – ACI 318, Section 9.6.1.3. [ACI 318 Modification]

Modify ACI 318, Section 9.6.1.3 by adding the following:

This section shall not be used for members that resist seismic loads, except for the following condition:

Foundation members designed for seismic load combinations including the overstrength factor in hospitals and correctional treatment centers.

The A_s provided shall not be less than that required by 1.2 times the cracking load based upon f_r defined in Section 19.2.3.

1905.1.2 – ACI 318, Section 11.2.4.1. [ACI 318 Replacement]

Replace ACI 318, Section 11.2.4.1 as follows:

11.2.4.1 – Walls shall be anchored to intersecting elements such as floors or roofs; or to columns, pilasters, buttresses, of intersecting walls and footings with

reinforcement at least equivalent to No. 4 bars at 12 inches (305 mm) on center for each layer of reinforcement.

1905.1.3 – ACI 318, Section 12.7.3 [ACI 318 Addition]

Add Section 12.7.3.4 to ACI 318 as follows:

12.7.3.4 - At least two No. 5 bars in diaphragms having two layers of reinforcement in both directions and one No. 5 bar in diaphragms having a single layer of reinforcement in both directions must be provided around openings larger than 12 inches in any dimension in addition to the minimum reinforcement required by Section 12.6. Extend bars beyond the opening sufficient to develop their capacity.

1905.1.5 – ACI 318, Section 18.12.6 [ACI 318 Addition]

Add Section 18.12.6.2 to ACI 318 as follows:

18.12.6.2 – Collector and boundary elements in topping slabs placed over precast floor and roof elements shall not be less than 3 inches (76 mm) or $6d_b$ thick, where d_b is the diameter of the largest reinforcement in the topping slab.

1905.1.6 – ACI 318, Section 26.12.2.1(a). [ACI 318 Replacement]

Replace ACI 318 Section 26.12.2.1(a) by the following:

26.12.2.1(a) Samples for strength tests of each class of concrete placed each day shall be taken not less than once a day, or not less than once for each 50 cubic yards (345 m³) of concrete, or not less than once for each 2,000 square feet (186 m²) of surface area for slabs or walls. Additional samples for 7-day compressive strength tests shall be taken for each class of concrete at the beginning of the concrete work or whenever the mix or aggregate is changed.

6-5 IBC CHAPTER 21 – MASONRY.

6-5.1 Section 2101 – GENERAL.

2101.1.1 – Prohibition [Addition]

The following design methods, systems, and materials in TMS 402-16 are not permitted:

- 1 Unreinforced masonry
- 2 Autoclaved aerated concrete (AAC) masonry
- 3 Empirical design of masonry
- 4 Adobe construction
- 5 Ordinary reinforced masonry shear walls

- 6 Intermediate reinforced masonry shear walls
- 7 Prestressed masonry shear walls
- 8 Simplified Direct Design procedure for masonry

6-5.2 Section 2106 – SEISMIC DESIGN.

2106.1.1 – TMS 402-16, Sections 5.3.1.4(a) and 5.3.1.4(b) [IBC Addition, TMS Replacement]

Replace TMS 402-16, Sections 5.3.1.4(a) and 5.3.1.4(b) as follows:

- a. Ties must be at least 3/8 inch (10 mm) in diameter and must be embedded in grout. Top tie must be within 2 inches (51 mm) of the top of the column or of the bottom of the horizontal bar in the supported beam.
- b. The spacing of column ties must be as follows: not greater than 8 bar diameters, 24 tie diameters, or one half the least dimension of the column, or 8 inches (203 mm) for the full column height.

2106.1.2 – TMS 402-16, Chapter 5 [IBC Addition, TMS Addition]

Add TMS 402-16, Section 5.6 as follows:

5.6 – Lateral Support of Members

5.6.1 – Lateral support of masonry may be provided by cross walls, columns, plasters, counterforts or buttresses where spanning horizontally, or by floors, beams, girts or roofs where spanning vertically. Where walls are supported laterally by vertical elements, the stiffness of each vertical element shall exceed that of the tributary area of the wall.

2106.1.3 – TMS 402-16, Sections 7.4.4.1 and 7.4.5.1. [IBC Addition, TMS Replacement, Deletion]

Replace TMS 402-16, Section 7.4.4.1 as follows and delete Section 7.4.5.1:

7.4.4.1 – Minimum Reinforcement Requirements for Masonry Walls.

The total area of reinforcement in reinforced masonry walls must not be less than 0.003 times the sectional area of the wall. Neither the horizontal nor the vertical reinforcement is permitted to be less than one third of the total. Horizontal and vertical reinforcement must be spaced at not more than 24 inches (610 mm) center to center. Where stack bond is used in reinforced hollow-unit masonry, the open-end type of unit shall be used with vertical reinforcement spaced a maximum of 16 inches (406 mm) on center.

7.4.4.1.1 The smallest bar diameter permitted is No. 4, except that No. 3 bars may be used for ties and stirrups. Vertical wall reinforcement needs to have dowels of equal size and equal matched spacing in all footings. Reinforcement must be continuous around wall corners and through intersections. Only reinforcement that is continuous in the wall is permitted in computing the minimum area of reinforcement. Reinforcement with splices conforming to TMS 402-16 can be considered as continuous reinforcement.

7.4.4.1.2 Horizontal reinforcing bars in bond beams must be provided at the top of footings, at the top of wall openings, at roof and floor levels, and at the top of parapet walls. For walls 12 inches (nominal) (305 mm) or more in thickness, horizontal and vertical reinforcement must be equally divided into two layers, except where designed as retaining walls. Where reinforcement is added above the minimum requirements, such additional reinforcement need not be so divided.

7.4.4.1.3 Provide trim bars around openings in reinforced masonry walls of not less than one number 5 bar (or two number 4 bars) for all openings greater than 24 inches (406mm) in any direction. Extend said trim bars 24 inches or 48 bar diameters beyond the corners of the opening, whichever is greater. Trim bars noted in this requirement are in addition to minimum reinforcement elsewhere.

7.4.4.1.4 When reinforcement in bearing walls is designed, placed, and anchored in position as for columns, the allowable stresses must be as for columns.

7.4.4.1.5 Joint reinforcement is not permitted to be used as principal reinforcement in masonry.

6-5.3 Section 2107 - ALLOWABLE STRESS DESIGN.

2107.4 – TMS 402-16, Section 8.3.4.4 Walls [IBC Addition, TMS Supplement]

Modify TMS 402-16, Section 8.3.4.4 as follows by adding:

8.3.4.4.1 The minimum thickness of walls is given in Section 8.3.4.4.2. Stresses must be determined on the basis of the net thickness of the masonry, with consideration for reduction, such as raked joints.

8.3.4.4.2 The thickness of masonry walls must be designed so that allowable maximum stresses specified in Chapter 8 of TMS 402-16 are not exceeded. Also, masonry walls are not permitted to exceed the height or length-to-thickness ratio nor be less than the minimum thickness as specified in Chapter 8 of TMS 402-16 and as set forth in Table 6-1.

8.3.4.4.3 Every pier or wall section with a width less than three times its thickness shall be designed and constructed as required for columns if such pier is a structural member. Every pier or wall section with a width between three and five times its thickness or less than one half the height of adjacent openings shall

have all horizontal steel in the form of ties except that in walls 12 inches (305 mm) or less in thickness such steel may be in the form of hairpins.

2107.5 – Masonry Compressive Strength [IBC Addition]

The specified compressive strength of structural masonry must be equal to or exceed 1,500 psi (10.34 MPa). The value of specified compressive strength used to determine nominal strength value in Chapter 8 of TMS 402-16 must not exceed 3,000 psi (20.7 MPa) for concrete masonry and must not exceed 4,500 psi (31.03 MPa) for clay masonry.

6-5.4 Section 2108 – STRENGTH DESIGN OF MASONRY.

2108.4 – TMS 402, Section 9.1.9.1.1.[IBC Addition, TMS Modification]

Modify TMS 402, Section 9.1.9.1.1 as follows:

9.1.9.1.1 – Masonry Compressive Strength. The specified compressive strength of structural masonry must be equal to or exceed 1,500 psi (10.34 MPa). The value of specified compressive strength used to determine nominal strength value in chapter 9 of TMS 402-16 must not exceed 3,000 psi (20.7 MPa) for concrete masonry and must not exceed 4,500 psi (31.03 MPa) for clay masonry.

6-6 IBC CHAPTER 22 – STEEL.

6-6.1 Section 2204 – CONNECTIONS.

2204.1.1 – Restrained Welded Connections. [Addition]

In hospitals and correctional treatment centers, welded structural steel connections having a medium or high level of restraint, as defined by AWS D1.1 Annex H, shall have a minimum pre-heat temperature of not less than 150° F (66° C). Welded structural steel connections with welds to flange, web, wall or plate having a high level of restraint shall maintain a post-heat temperature of 300° F (149° C) for a minimum of 1 hour after completion of welding

2204.4 – Column Base Plate. [Addition]

When shear and/or tensile forces are intended to be transferred between column base plates and anchor bolts, provisions shall be made in the design to eliminate the effects of oversized holes permitted in base plates by AISC 360 by use of shear lugs into the reinforced concrete foundation element and/or welded shear transfer plates or other means acceptable to the Authority Having Jurisdiction, when the oversized holes are larger than the anchor bolt by more than 1/8 inch (3.2 mm). When welded shear transfer plates and shear lugs or other means acceptable to the Authority Having Jurisdiction are not used, the anchor bolts shall be checked for the induced bending stresses in combination with the shear stresses.

6-6.2 Section 2207 – STEEL JOISTS.

2207.6 – Joist Chord Bracing. [Addition]

The chords of all joists shall be laterally supported at all points where the chords change direction.

6-6.3 Section 2210 – COLD-FORMED STEEL.

2210.1.1.2 – Steel Roof Deck [Supplement]

Add the following to the end of the paragraph:

In hospitals and correctional treatment centers, steel roof deck is not permitted to be thinner than 20-gauge.

6-6.4 Section 2211 – COLD-FORMED STEEL LIGHT-FRAMED CONSTRUCTION.

2211.1.2 – Prescriptive Framing [Replacement]

Prescriptive framing systems are not permitted within the seismic force-resisting system of a building.

Table 6-1 Minimum Thickness of Masonry Walls^{1,2}

Type of Masonry	Maximum Ratio of Unsupported Height or Length to Thickness ^{2,3}	Nominal Minimum Thickness (Inches)
Bearing or Shear Walls:		
1. Stone masonry	14	16
2. Reinforced grouted masonry	25	6
3. Reinforced hollow unit masonry	25	6
Nonbearing Walls:		
4. Exterior reinforced walls	30	6
5. Interior reinforced partitions	36	4

1. For varying thickness, use the least thickness when determining the height or length to thickness ratio.
2. In determining the height or length-to-thickness ratio of a cantilevered wall, use a dimension that is twice the dimension of the end of the wall from the lateral support.
3. Cantilevered walls not part of a building and not carrying applied vertical loads need not meet these minimum requirements but their design must comply with stress and overturning requirements.

CHAPTER 7 MODIFICATIONS TO ASCE 7-16 FOR CRITICAL HEALTHCARE FACILITIES

This Chapter adopts some of the modifications made by Section 1617A of the 2022 California Building Code to ASCE 7-16 for DoD's critical healthcare facilities. The 2022 CBC is based on the 2021 IBC. The 2025 CBC, based on the 2024 IBC, was not available when this Chapter was finalized. So, any reference to IBC in this Chapter is to the 2021 IBC and its referenced standards: ASCE 7-16, ACI 318-19, TMS 402-16, AISC 360-16, and AISC 341-16. This Chapter will need to be updated once the 2025 CBC is published.

7-1 ASCE 7-16 CHAPTER 11 – SEISMIC DESIGN CRITERIA.

7-1.1 Section 11.1 – GENERAL.

11.1.2 – Scope [Supplement]

For the facilities listed below and assigned to SDC D, E, or F, the modifications to ASCE 7-16 included in this chapter apply in addition to those in Chapter 3 of this UFC. Where the provisions of this chapter and those in ASCE 7-16 or in Chapter 3 of this UFC are in conflict, the provisions of this chapter govern.

- Group I-2, Condition 2 occupancies, as defined in 2021 IBC Section 308.3, having emergency surgery or emergency treatment facilities.
- Ambulatory care facilities having emergency surgery or emergency treatment facilities.

7-2 ASCE 7-16 CHAPTER 12 – SEISMIC DESIGN REQUIREMENTS FOR BUILDING STRUCTURES.

7-2.1 Section 12.1 – STRUCTURAL DESIGN BASIS.

12.1.7 – Structural Configuration. [Addition]

The following configuration limitations apply to structures within the scope of this chapter.

1. Bay spacing must be essentially equal and uniform throughout.
2. Transfer beams or trusses supporting upper-level columns are not to be used unless permitted on a case by case basis by the AHJ.
3. Seismic joints must be avoided, if at all possible. When required, they need to be specifically identified in the schematic design phase of the project and approved by the AHJ, subject to the following provisions:
 - a. Seismic joints must be properly detailed on the working drawings;

- b. Seismic joints must be sized based on the maximum expected displacements, considering the effects of story drift, diaphragm displacements and rotations, and a realistic approximation of element section properties. For materials designed considering the ultimate limit state, such as concrete, the stiffness representative of this state must be used. Seismic separations must be at least 125% of the separation required by ASCE 7-16.
4. Adjacent structures that are not integral with an existing structure must be separated by not less than 2 inches per story.

12.1.8 – Limitations on Seismic Force-Resisting Reinforced Concrete Structural Members. [Addition]

Lightweight concrete is not permitted to be used in structural members resisting seismic forces, except in concrete floors and roof slabs used as diaphragms to distribute earthquake forces to vertical seismic force-resisting members.

12.1.9 – Limitations on Seismic Force-Resisting Steel Structural Members. [Addition]

Steel eccentrically braced systems must be subject to the additional limitation that connections of nonstructural components are not to be located in the vicinity of EBF link beams. Such connections include, but are not limited to, precast panel connections, elevator guide rail supports, staircase supports, pipe supports, etc.

7-2.2 Section 12.2 – STRUCTURAL SYSTEM SELECTION.

12.2.1 – Selection and Limitations. [Supplement]

Table 7-1, Replacement for ASCE 7-16 Table 12.2-1, must be used in lieu of ASCE 7-16 Table 12.2-1. Only the structural systems included in Table 7-1 are permitted to be used in structures within the scope of this chapter.

Unless specifically prohibited in Chapter 6 of this UFC, other structural systems that are permitted by ASCE 7-16 for SDC D, E or F, including those employing seismic isolation and seismic damping systems are permitted subject to written approval by the AHJ. Proposals to obtain written approval for other structural systems must demonstrate the equivalent performance of those systems, relative to the permitted systems, considering (a) initial construction and maintenance costs, (b) requirements for bracing nonstructural components and building contents, (c) risk of economic losses and disruption to hospital functions due to earthquakes and (d) other demonstrable benefits.

12.2.3.1 – R , C_d , and Ω_o Values for Vertical Combinations. [Replacement]

Replace ASCE 7, Section 12.2.3.1, Items 1 and 2, by the following:

The value of the response modification coefficient, R , used for design at any story shall not exceed the lowest value of R that is used in the same direction at any story above that story. Likewise, the deflection amplification factor, C_d , and the system overstrength factor, Ω_o , used for the design at any story shall not be less than the largest value of these factors that are used in the same direction at any story above that story.

12.2.3.2 – Two-Stage Analysis Procedure. [Supplement]

Modify Item a, and add Items f, and g, as follows:

- a. The stiffness of the lower portion shall be at least 10 times the stiffness of the upper portion. For purposes of determining this ratio, the base shear shall be computed and distributed vertically according to ASCE 7-16 Section 12.8. Using these forces, the stiffness for each portion shall be computed as the ratio of the base shear for that portion to the elastic displacement, δ_{xe} , computed at the top of that portion, considering the portion fixed at its base. For the lower portion, the applied forces shall include the reactions from the upper portion, modified as required in Item d.
- f. Where Horizontal Irregularity Type 4 or Vertical Irregularity Type 4 exists at the transition from the upper to the lower portion, the reactions from the upper portion shall be amplified in accordance with ASCE 7-16 Sections 12.3.3.3, 12.10.1.1 and 12.10.3.3 as applicable, in addition to amplification required by Item d.
- g. Where design of members in the upper portion is governed by the seismic load effects with overstrength, as defined in ASCE 7-16 Section 12.4.3, the amplified loads must be considered in the design of the lower portion.

FOR SI: 1 foot (ft) = 304.8 mm, 1 pound per square foot (psf) = 0.0479 kN/m²

a. Response modification coefficient, R , for use throughout. Note R reduces forces to a strength level, not an allowable stress level.

b. Where the tabulated value of the overstrength factor, Ω_o , is greater than or equal to 2½, Ω_o is permitted to be reduced by subtracting the value of ½ for structures with flexible diaphragms.

c. Deflection amplification factor, C_d , for use in **ASCE 7** Sections 12.8.6, 12.8.7, 12.9.1.2, **12.12.3, and 12.12.4**.

d. NL= Not limited and NP = Not permitted. For metric units, use **30** m for 100 ft and **50** m for 160 ft.

e. See **ASCE 7-16** Section 12.2.5.4 for a description of seismic force-resisting systems limited to buildings with a structural height, h_n , of 240 feet (**75** m) or less.

f. See **ASCE 7-16** Section 12.2.5.4 for seismic force-resisting systems limited to buildings with a structural height, h_n , of 160 feet (**50** m) or less.

g. In Section 2.3 of ACI 318, a shear wall is defined as a structural wall.

h. In Section 2.3 of ACI 318, the definition of “special structural wall” includes precast and cast-in-place construction.

m. In Section 2.3 of ACI 318, the definition of “special moment frame” includes precast and cast-in-place construction.

r. **ANSI/AISC 341-16 section number.**

s. **ACI 318-19, Section 18.2.1.6 cites appropriate sections in ACI 318-19.**

t. **TMS 402-16 section number.**

u. **2021 IBC section numbers.**

v. **Permitted only for structures up to two-stories**

w. Structural height, h_n , shall not be less than 60 ft (18.3m).

7-2.3 Section 12.3 – DIAPHRAGM FLEXIBILITY, CONFIGURATION IRREGULARITIES, AND REDUNDANCY.

12.3.3.1 – Prohibited Horizontal and Vertical Irregularities for Seismic Design Categories D through F. [Replacement]

Structures having horizontal structural irregularity Type 1b of ASCE 7-16 Table 12.3-1 or vertical structural irregularities Type 1b, 5a or 5b of ASCE 7-16 Table 12.3-2 are not permitted.

7-2.4 Section 12.7 – MODELING CRITERIA.

12.7.3 – Additional Lateral Force [Addition]

Where buildings provide lateral support for walls retaining earth, and the exterior grades on opposite sides of the building differ by more than 6 feet (1829 mm), the seismic increment of earth pressure due to earthquake acting on the higher side, as determined by a geotechnical engineer qualified in soils engineering, plus the difference in earth pressures shall be added to the design lateral forces.

Renumber existing Sections 12.7.3 and 12.7.4 as 12.7.4 and 12.7.5, respectively.

7-2.5 Section 12.12 – DRIFT AND DEFORMATION.

12.12.3 – Structural Separation. [Replacement]

Replace ASCE 7-16 Equation 12.12-1 by the following:

$$\delta_M = C_d \delta_{max} \quad (\text{Equation 12.12-1})$$

7-3 ASCE 7-16 CHAPTER 13 – SEISMIC DESIGN REQUIREMENTS FOR NONSTRUCTURAL COMPONENTS.

7-3.1 Section 13.2 – GENERAL DESIGN REQUIREMENTS.

13.2.2 – Special Certification Requirements for Designated Seismic Systems [Supplement]

Special Seismic Certification must be provided in accordance with the requirements of ASCE 7-16 Section 13.2.2, except for equipment and components that are on the HCAI Special Seismic Certification Preapproval (OSP) list, issued by California's Department of Health Care Access and Information (HCAI).

Items prequalified under the Special Seismic Certification Preapproval (OSP) program of HCAI are deemed to possess Special Seismic Certification required by ASCE 7-16 Section 13.2.2.

[C] 13.2.2 – Special Certification Requirements for Designated Seismic Systems [Supplement]

HCAI has issued a Policy Intent Notice (PIN) 55 on its Special Seismic Certification Preapproval (OSP) program. This program offers a means to obtain prequalification of product lines for special seismic certification. Lists of equipment that is pre-approved by HCAI can be found at <https://hcai.ca.gov/facilities/building-safety/preapproval-programs/osp/> and <https://hcai.ca.gov/facilities/building-safety/preapproval-programs/osp-by-category/>. The basis of HCAI preapproval is always shake table testing in compliance with ICC-ES AC156 and satisfaction of ICC-ES AC156 post-test acceptance criteria.

7-3.2 Section 13.4 – NONSTRUCTURAL COMPONENT ANCHORAGE.

13.4.2.3 – Post-Installed Anchors in Concrete and Masonry [Replacement]

Revise section title to: **Prequalified Post-Installed Anchors and Specialty Inserts in Concrete and masonry.**

Replace text with: Post-installed anchors and specialty inserts in concrete that are prequalified for seismic applications in accordance with ACI 355.2, ACI 355.4, ICC-ES AC193, ICC-ES AC232, ICC-ES AC308 or ICC-ES AC446 are permitted. Post-installed anchors in masonry must be pre-qualified for seismic applications in accordance with ICC-ES AC01, AC58 or AC106.

Use of screw anchors is limited to dry interior conditions. Screw anchors are not permitted for use in building exterior envelopes. Re-use of screw anchors or screw anchor holes is not permitted.

7-3.3 Section 13.5 – ARCHITECTURAL COMPONENTS.

13.5.7 – Access Floors [Supplement]

In hospitals and correctional treatment centers, all access floors must be special access floors in accordance with ASCE 7-16 Section 13.5.7.2, except for raised roof or exterior floor paver systems.

7-3.4 Section 13.6 – MECHANICAL AND ELECTRICAL COMPONENTS.

13.6.11.1.1 – Elevator guide rail support. [Addition]

The design of guide rail support-bracket fastenings and the supporting structural framing must use the weight of the counterweight or maximum weight of the car plus not less than 40 percent of its rated load. The seismic forces must be assumed to be distributed one third to the top guiding members and two thirds to the bottom guiding members of cars and counterweights, unless other substantiating data are provided. In addition to the requirements of ASCE 7-16,

Section 13.6.11.1, the minimum ASD-level seismic forces must be 0.5g acting in any horizontal direction.

7-4 ASCE 7-16 CHAPTER 17 – SEISMIC DESIGN REQUIREMENTS FOR SEISMICALLY ISOLATED STRUCTURES.

7-4.1 Section 17.4 – ANALYSIS PROCEDURE SELECTION.

17.4.2.3 – Linear Procedures [Addition]

Linear procedures must not be used in Seismic Design Category E or F structures.

7-5 ASCE 7-16 CHAPTER 18 – SEISMIC DESIGN REQUIREMENTS FOR STRUCTURES WITH DAMPING SYSTEMS.

18.3 – Nonlinear Response History Procedure [Supplement]

Add the following to the Exception:

For this section, the MCE_R response shall be based on the largest response due to a single ground motion and not the average response of a suite of ground motions.

APPENDIX A BEST PRACTICES

A-1 STRUCTURAL DESIGN.

A-1.1 Building Drift Limits.

The topic of serviceability is addressed in IBC Section 1604.3 which requires: “Structural systems and members thereof shall be designed to have adequate stiffness to limit deflections as indicated in Table 1604.3.” Section 1604.3.1 requires: “The deflections of structural members shall not exceed the more restrictive of the limitations of Sections 1604.3.2 through 1604.3.5 or that permitted by Table 1604.3.” Sections 1604.3.2 through 1604.3.5 refer to ACI 318 requirements for concrete, AISC 360, AISI S100, ASCE 8, SJI 100 or SJI 200 requirements for steel, TMS 402 requirements for masonry, and AA ADM requirements for Aluminum. However, the section is obviously focused on structural members, not an entire building or structure.

ASCE 7-22 Section 12.12 requires interstory drift caused by code-prescribed seismic forces to be within tolerable limits as obtained from Table 12.12-1. These are the only mandatory building drift limits of the IBC.

ASCE 7-22 Appendix C, Serviceability Considerations, which is non-mandatory, states in Section C.2.2: “Lateral deflection or drift of structures and deformation of horizontal diaphragms and bracing systems caused by wind effects must not impair the serviceability of the structure.” The extensive commentary on this appendix discusses how the above objective might be accomplished, but leaves it to engineering judgment that should be exercised in consultation with the building owner.

The establishment of acceptable drift limits and load combinations that must be considered in evaluating serviceability does require significant engineering judgment. Application of a requirement that is overly stringent can significantly impact the cost of a structure. Lax requirements, on the other hand, can lead to damage of rigidly connected components.

The *Metal Building Systems Manual* provides guidance on allowable drift due to wind loads for pre-engineered metal buildings, and serviceability recommendations for metal buildings can also be found in Chapter L of AISC 360 with additional guidance in AISC *Steel Design Guide 3*.

When separate support columns are used for top-running cranes, they should be supported so that differential movement between the crane columns and building columns, due to differences in stiffness, does not overstress either set of columns and result in local column buckling.

A-1.2 Impact Resistant Glazing.

Buildings that are subjected to tornado winds can suffer some of the same missile impact damage to the exterior façade of the building as those located in windborne debris regions. The loss of glazing on a building due to missile impact can render the facility

inoperable. The loss of glazing will also cause an increase in internal pressure in the building, causing further damage. ASCE 7-22 has added a whole new Chapter 32 on design for tornado loads. Tornado-Prone Region is defined in Section 32.2 as “The area of the conterminous United States most vulnerable to tornadoes, as shown in Figure 32.1-1.” Section 32.12.3 is applicable in tornado-prone regions and requires: “Glazed openings shall be protected as specified in this section for Essential Facilities and for buildings and other structures required to maintain the functionality of Essential Facilities.” Protection requirements for glazed openings are given in Section 32.12.3.1. Design for tornado loads given in Chapter 32 is not required for RC I or II structures. Consideration should be given to providing impact resistant glazing on facilities that are not covered by Section 32.12.3 in tornado prone areas similar to what is required in wind-borne debris regions as specified in IBC Section 1609.2.

A-1.3 Hard Wall Buildings.

In buildings constructed of load bearing tilt-up or precast structural walls, the loss of the roof diaphragm during a high wind event can lead to total collapse of the structure.

FEMA has issued an important publication, FEMA P-1026, on the seismic design of these buildings. ASCE 7-22 has added Section 12.10.4, based on the FEMA P-1026 document.

A-1.4 Wind and Seismic Loads on Photovoltaic Arrays.

Design provisions for rooftop-mounted photovoltaic panels and their attachments are included in ASCE 7-22 Section 13.6.12 for seismic loading and in ASCE 7-22 Chapters 29 through 31 for wind loading. Additional guidance on the design wind and seismic loads for rooftop-mounted photovoltaic arrays can be found in *Wind Design for Solar Arrays* (SEAOC PV2-2017) and *Structural Seismic Requirements and Commentary for Rooftop Solar Photovoltaic Arrays* (SEAOC PV1-2012), prepared by the Structural Engineers Association of California Solar Photovoltaic Systems Committee. When designing support structures for photovoltaic arrays, review requirements in UFC 3-110-03 *Roofing* concerning roof mounted systems including the requirement that supports be permanently affixed to the structure, which means that ballasted systems are not permitted. 2024 IBC Section 1607.14.4 includes gravity load requirements for roof structures that provide support for photovoltaic panel systems. This section does not disallow ballasted systems. Seismic design of ballasted photovoltaic panel systems is in fact specifically permitted by 2024 IBC Section 1613.3.

A-1.5 Wind Loads on Buildings with Large Openings.

When determining wind loads on building containing large openings such as overhead doors in warehouses, maintenance shops, etc., it is recommended that the criteria for hangars in Section 1609.1.2 of Chapter 2 of this UFC be used.

A-2 SOILS AND FOUNDATIONS.

A-2.1 Gable Bent Footings.

Moment frame reactions from metal building gable bents have horizontal thrusts at column bases which can be resisted by several methods. For large thrust forces (40 to 50 kips (118 kN to 222 kN)), tie rods are usually cost-effective. The tie rods can be embedded in a thickened slab or can be part of a tie beam between column foundations. For smaller thrust forces, hairpin reinforcing bars may be used to transfer the thrust force from the column anchor bolts into the slab-on-ground reinforcement, which acts as the tie between the columns. However, each of these methods requires close attention to detailing of joints in the slab, isolation joints around a foundation pier and other possible interruptions in the continuous slab reinforcement between columns. Also, future renovations that might require trenching across the continuous slab reinforcement could result in the loss of the tension tie. A third method must design the foundation for an overturning moment due to the thrust force at the base of the column. Each of these methods can provide the necessary resistance to the thrust force but needs to be evaluated for each project condition. For further discussion on the design of foundations for gable bent reactions, refer to *Metal Building Systems: Design and Specification* by Alexander Newman.

A-2.2 Footings on Expansive Soils.

In the presence of expansive soils, footings must be designed to withstand expansive soil movement in order to prevent significant damage to structures. Cyclical expansive soil movement from soil water content, usually caused by a combination of inadequate drainage and seasonal wetting and drying cycles, are especially troublesome. Base the design on soil testing and recommendations by qualified geotechnical engineers. Ensure soil investigations include estimates of settlement, heave, and recommendations to mitigate effects of expansive soil movement. Ensure positive drainage away from structures that will prevent ponding close to structures. Guidance on design of foundations on expansive soils can be found in UFC 3-220-01 and PTI DC 10.5-21.

A-2.3 Footing Depth Considering Frost.

Footing depth for frost must be provided by the project geotechnical engineer

A-3 CONCRETE.

A-3.1 Slab-on-Ground Concrete Strength.

Reference guidance in “*Design of Concrete Floor Slabs-on-Ground for DoD Facilities*” under Related Materials for this UFC (WBDG page for 3-301-01).

A-3.2 Slab-on-Ground Joints.

Reference guidance in “*Design of Concrete Floor Slabs-on-Ground for DoD Facilities*” under Related Materials for this UFC (WBDG page for 3-301-01).

A-3.3 Slab-on-Ground Drying Shrinkage.

Reference guidance in “Design of Concrete Floor Slabs-on-Ground for DoD Facilities” under Related Materials for this UFC (WBDG page for 3-301-01).

A-3.4 Slab-on-Ground Vapor Retarder/Barrier.

Reference guidance in “Design of Concrete Floor Slabs-on-Ground for DoD Facilities” under Related Materials for this UFC (WBDG page for 3-301-01).

A-4 MASONRY.

A-4.1 Masonry Veneer Base Detail.

The base of masonry veneer should be placed on a foundation ledge that is lower than the base of the stud wall by at least 4 inches (102 mm). The width of this foundation ledge will include the width of the masonry veneer and the cavity. This width should not be less than two-thirds of the veneer thickness plus the minimum air space.

A-5 STEEL.

A-5.1 Shelf Angles for Masonry.

Shelf angles should be hot-dip galvanized structural steel members. Angles should be provided in segments approximately 10 feet (3 m) in length, with gaps between segments. Shelf angles should be detailed to allow enough gaps for thermal expansion and contraction of the steel in angle runs and at building corners. Corners of buildings should have corner pieces with each leg no less than 4 feet (1.2 m) in length where possible.

Limit deflection of horizontal legs of shelf angles under masonry loading to 1/16 inch (1.6 mm) at the end of the horizontal leg. Rotation of the shelf angle support should be included in the horizontal leg displacement calculation.

A-5.2 Cold-Formed Continuous Beams and Joists.

Guidance on determining the effective length of the unbraced compression flange for cold-formed continuous beams and joists can be found in AISI *Effective Lengths for Laterally Unbraced Compression Flanges of Continuous Beams Near Intermediate Supports*.

A-5.3 Masonry Veneer/Steel Stud Wall Detailing.

Recommended details for masonry veneer/steel stud wall assemblies can be found in BIA Technical Note 28B.

A-5.4 Steel Structures in Corrosive Environments.

Steel structures designed for corrosive environments should include consideration of the following corrosion protection measures:

- a. Box-shaped members should be designed so that all inside surfaces may be readily inspected, cleaned, and painted, or should be closed entirely, except when hot-dip galvanized, to prevent exposure to moisture.
- b. The legs of two back-to-back angle members, when not in contact, should have a minimum separation of 3/8 inch (9.5 mm) to permit air circulation.
- c. Pockets or depressions in horizontal members should have drain holes to prevent water from ponding in low areas. Positive drainage should be provided away from exposed steel. Column bases should be terminated on concrete curbs or piers above grade, and tops of curbs or piers should be pitched to drain.
- d. Where extremely corrosive conditions exist, consideration should be given to providing cathodic protection in addition to protective coatings for steel members exposed to saltwater moisture environments.
- e. Structural members embedded in concrete and exterior railing, handrails, fences, guardrails, and anchor bolts should be galvanized or constructed of stainless steel.
- f. Dissimilar metals, (e.g., aluminum and steel, stainless steel and carbon steel, zinc-coated steel and uncoated steel) should be isolated by appropriate means to avoid the creation of galvanic cells which can occur when dissimilar metals come in contact.
- g. Consult a corrosion specialist certified by NACE International to recommend material protection for elements exposed to heavy industrial pollution, chemicals, or corrosive soils.
- h. For increased serviceability and compatibility with fireproofing, use galvanized steel deck in accordance with ASTM A653/A653M.
- i. Note that some common grades of stainless alloy such as ASTM A306 or A316 are susceptible to corrosion when immersed in salt or brackish water.

Further guidance for designing steel structures in corrosive environments can be found in ASM [formerly, American Society of Metals] *Handbook Volume 13B*.

A-5.5 Steel Structures in Arctic and Antarctic Zones.

For carbon steel, the transition from ductile to brittle behavior occurs within temperatures to be expected in Arctic and Antarctic zones. Ductility is important for structures in high seismic areas. Toughness, a characteristic also affected by cold temperatures, is important for structures which could be subjected to cyclic or impact loads. Design of structures which could be subjected to cyclic or impact loads in cold climates should include consideration of the following measures to mitigate potential fatigue and fracture problems:

- a. Provide ample fillets to avoid stress risers.
- b. Use bolted joints whenever possible. If welded joints are used, take precautions to eliminate gas and impurities in welds. Proper preheating and post-cooling are essential.
- c. Use low-carbon steels and nickel-alloy steels that have good toughness characteristics at low temperatures.

A-5.6 Steel Column Base Plate Shear Transfer.

Shear transfer between column base plates and the concrete foundation elements can be accomplished through several load paths including shear friction between the base plate and grout, anchor rods or shear keys. The design provisions in AISC *Design Guide 1: Base Plate and Anchor Rod Design* should be followed when designing base plates for shear. Research and full-scale testing of base plates in shear, conducted at the University of California, Berkeley, provide further guidance on recommended shear friction coefficient, anchor rod bending length, and concrete capacity design of shear key bearing. Results of the testing can be found in the research report *Shear Transfer in Exposed Column Base Plates*, published by AISC.

A-5.7 Steel Joist Connections.

Connections between open web steel joists and supporting girders or joist girders and building columns are in many instances covered by typical details provided by the joist supplier, which may not provide the needed capacity for lateral or uplift loading. Each joist connection should be designed specifically for the project and take into consideration the lateral and uplift loads acting on the connection.

A-6 WOOD.

A-6.1 Connections.

When using prescriptive guidelines in building codes for nailed wood connections, careful consideration needs to be given to ensuring a complete load path from the roof to the foundation. The use of metal plate connections for roof trusses, top plates and sill plates is an effective way to provide a more robust load path.

APPENDIX B ALTERNATE DESIGN PROCEDURE FOR BUILDINGS AND OTHER STRUCTURES IN RISK CATEGORY IV

B-1 GENERAL.

B-1.1 Overview.

This Appendix may be used for the alternate design of buildings and other structures assigned to RC IV.

Buildings assigned to RC IV are either unit/installation-essential or post-disaster essential (Table 2-2). This Appendix provides an optional nonlinear static and nonlinear dynamic analysis procedure for RC IV buildings and other structures that may be used as an alternative to the procedures found in the 2024 *International Building Code* (2024 IBC). This Appendix references the 2017 edition of ASCE/SEI 41, *Seismic Evaluation and Retrofit of Existing Buildings* (herein-after referred to simply as ASCE 41-17). This procedure may provide more economical or better-performing structural designs compared to linear analysis procedures. The analysis procedures outlined in this Appendix are to be used only with the approval of the Authority Having Jurisdiction.

The nonlinear procedures outlined in this Appendix require that an RC IV building meet two general structural performance objectives:

1. A Life Safety (LS) performance level for the Risk-Targeted Maximum Considered Earthquake (MCE_R) ground motions, nominally an earthquake associated with a 1% probability of structural collapse in 50 years; and,
2. An Immediate Occupancy (IO) performance level for earthquake ground motion that is two-thirds of the MCE_R ground motion. This earthquake is termed herein as the BSE-1N earthquake, adopting the terminology used in ASCE 41-17.

The procedures in this Appendix also require that the nonstructural components in an RC IV building meet the following two performance objectives:

1. A Hazard Reduced (HR) performance level for the Risk-Targeted Maximum Considered Earthquake (MCE_R) ground motion; and,
2. An Operational (OP) performance level for earthquake ground motion that is two-thirds of the MCE_R ground motion.

Performance criteria based on tolerable levels of damage are defined to ensure that these performance objectives are met. Nonlinear strength and deformation demands are determined by performing nonlinear static or nonlinear dynamic analyses and the results compared with acceptance criteria contained in authoritative documents, such as ASCE 41-17 or FEMA P-750 or developed based on laboratory data or rational analysis.

To ensure that satisfactory nonlinear behavior is achieved, restrictions are imposed on the types of seismic force-resisting systems that can be used in conjunction with this Appendix.

This Appendix replaces the provisions of Chapter 16 of the 2024 IBC, as modified by Chapter 2 of this UFC, for use in performing the alternative analysis of RC IV buildings and other structures. All other chapters of the 2024 IBC apply as modified by Chapter 2 of this UFC.

[C] B-1.1 Overview

In ASCE 7-22, MCE_R is used in conjunction with a “Collapse Prevention” performance objective. The alternate design in this chapter is required to meet a “Life Safety” performance objective. So, from a purist point of view, the procedure in this Appendix should have used MCE ground motion values, which could be determined by dividing the S_S - and S_1 - values of ASCE 7-22, by risk coefficients C_{RS} (ASCE 7-22 Figure 22-18) and C_{R1} (ASCE 7-22 Figure 22-19), respectively. In view of the fact that C_{RS} - and C_{R1} -values are typically within a narrow range around 1.0, a decision was made to avoid unjustifiable complications and use MCE_R ground motion in place of MCE ground motion for the alternative designs of this Appendix. The same approach is adopted in ASCE 41-17 as well.

The Life Safety (LS) and Immediate Occupancy (IO) performance levels for structural members at MCE_R and BSE-1N ground motions, respectively, are consistent with Table 4.1(a) of this UFC, RP10 Table 2.2 and ASCE 41-17 Table 2.3.

In the past, the performance levels for the nonstructural components were Life Safety (LS) and Immediate Occupancy (IO) at MCE_R and BSE-1N ground motions, respectively. In this UFC, the performance levels are changed to Hazard Reduced (HR) and Operational (OP) at MCE_R and BSE-1N ground motions, respectively, to be consistent with Table 4.1(b) of this UFC, RP10 Table 2.2 and ASCE 41-17 Table 2.3.

B-1.2 Design Review Panel.

A design review of the seismic force-resisting system design and structural analysis must be performed by an independent team of Registered Design Professionals in the appropriate disciplines and others experienced in seismic analysis methods and the theory and application of nonlinear seismic analysis and structural behavior under extreme cyclic loads. In addition to a final review, a Design Review Panel should be convened at the beginning of a design to review proposed design methodology and strategy. Membership on the Design Review Panel is subject to the approval of the Authority Having Jurisdiction. A design review needs to include, but not necessarily be limited to, the following:

1. Any site-specific seismic criteria used in the analysis, including the development of site-specific spectra and ground motion time-histories;
2. Any acceptance criteria used to demonstrate the adequacy of structural elements and systems to withstand the calculated force and deformation demands, together with any laboratory or other data used to substantiate the criteria;
3. The preliminary design, including the selection of the structural system and the configuration of structural elements; and,
4. The final design of the entire structural system and all supporting analyses.

B-2 DEFINITIONS.

B-2.1 General.

2024 IBC Section 202 and ASCE 7-22 Section 11.2 apply. In addition, the definitions listed in Section X.1 of Resource Paper 2 of FEMA P-750, *NEHRP Recommended Provisions for Seismic Regulations for New Buildings and Other Structures*, 2009 Edition, apply.

B-3 CONSTRUCTION DOCUMENTS.

B-3.1 General.

2024 IBC Section 1603, as modified by Section 2-4.1 of this UFC, applies.

Exception:

For buildings designed using this Appendix, the Seismic Importance Factor, I_e , the design base shear, seismic response coefficient, C_s , and the Response Modification Factor, R , do not apply and need not be listed in construction documents.

B-4 GENERAL DESIGN REQUIREMENTS.

B-4.1 General.

2024 IBC Section 1604 applies, except as modified herein. Table 2-2 of this UFC must replace 2024 IBC Table 1604.5. The Importance Factor for seismic loading defined in Table 2-2 does not apply and should be taken as 1.0. Importance Factors for seismic design of nonstructural components must be determined in accordance with the criteria of ASCE 7-22 Chapter 13. Importance Factors for snow and ice loads are no longer used in ASCE 7-22.

B-5 LOAD COMBINATIONS.

B-5.1 General.

RC IV buildings and other structures, and portions thereof, must be designed to resist the load combinations specified in this section. For all load combinations where earthquake-generated forces are not considered, ASCE 7-22 Section 2.3 applies. Where earthquake-generated forces are considered, ASCE 7-22 Section 2.3.6 load combinations 6 and 7, must be replaced by Equations B-1 and B-2 of this UFC. ASCE 7-22 Section 2.4 and 2024 IBC Section 1605.2 do not apply; allowable stress design is not permitted for use in this Appendix. The load combinations in ASCE 7-22 Section 2.3.6 that include seismic load effect with overstrength, E_m , does not apply; for any design situation requiring the use of load combinations with overstrength factor, Equations B-1 and B-2 apply, subject to the exceptions noted in Section B-18.1.

B-5.2 Seismic Load Combinations.

When the effects of earthquake-generated forces are considered, structures are required to resist the most critical effects from the following combinations of factored loads:

When the effects of gravity and seismic loads are additive:

$$1.1(D + 0.25 L + 0.15 S) + E \quad \text{(Equation B-1)}$$

When the effects of gravity and seismic loads are counteractive:

$$0.9 D + E \quad \text{(Equation B-2)}$$

Where

D = Effect of dead load

L = Effect of unreduced design live load

S = Effect of design flat roof snow load calculated in accordance with ASCE 7-22 for a Risk Category IV building.

E = The effect of horizontal and vertical earthquake forces at the BSE-1N displacement (Δ_S) or MCE_R displacement (Δ_M), determined in the nonlinear analysis, as set forth in Section B-18.1.

Exception: Where the design flat-roof snow load calculated in accordance with ASCE 7-22 is less than 40 psf, the effective snow load is permitted to be taken as zero.

B-6 DEAD LOADS.

B-6.1 General.

2024 IBC Section 1606 applies.

B-7 LIVE LOADS.

B-7.1 General.

2024 IBC Section 1607, as modified by Section 2-4.4 of this UFC, applies, except that wherever Table 1607.1 is referenced, it must be replaced by Table E-1 of this UFC.

B-8 SNOW LOADS.

B-8.1 General.

2024 IBC Section 1608, as modified by Section 2-4.5 of this UFC, applies.

B-9 WIND LOADS.

B-9.1 General.

2024 IBC Section 1609, as modified by Section 2-4.6 of this UFC, applies.

B-10 SOIL LOADS AND HYDROSTATIC PRESSURE.

B-10.1 General.

2024 IBC Section 1610 applies, without the exception in Section 1610.1.

B-11 RAIN LOADS.

B-11.1 General.

2024 IBC Section 1611 applies.

B-12 FLOOD LOADS.

B-12.1 General.

2024 IBC Section 1612 applies.

B-13 ICE LOADS—ATMOSPHERIC ICING.

B-13.1 General.

2024 IBC Section 1614 applies.

B-14 TSUNAMI LOADS.

B-14.1 General.

Probabilistic Tsunami Hazard Analysis (PTHA) may be performed on either the current topography or the topography adjusted for sea level rise. Use current NAVD88 [North American Vertical Datum of 1988]/MHW still water elevation for EGL (Energy Grade Line) velocity calculations regardless of topography used for PTHA.

B-15 EARTHQUAKE LOADS – GENERAL.

B-15.1 Scope.

Every structure, and portion thereof, shall as a minimum be designed and constructed to resist the effects of earthquake motions and assigned an SDC as set forth in 2024 IBC Section 1613.2.5/ASCE 7-22 Section 11.6. The use of nonlinear analysis procedures in this Appendix minimizes the need for SDC use, but the SDC is required for establishing detailing requirements.

B-16 EARTHQUAKE LOADS – SITE GROUND MOTION.

B-16.1 Determining MCE_R and BSE-1N Response Spectra and Spectral Response Accelerations.

Where an MCE_R response spectrum is required, the Multi-Period 5% damped MCE_R response spectrum from the USGS Seismic Design GeoDatabase for the applicable site class should be used.

Exceptions:

1. Where a site-specific ground motion analysis is performed in accordance with Section 11.4.7, the response spectrum shall be determined in accordance with Section 21.2.3.
2. Where values of the Multi-Period 5% damped MCE_R response spectrum are not available USGS Seismic Design GeoDatabase, the MCE_R response spectrum shall be permitted to be determined in accordance with Section 11.4.5.2, with S_{MS} and S_{M1} substituted for S_{DS} and S_{D1} respectively.

S_{MS} and S_{M1} values can be obtained directly from the USGS Seismic Design GeoDatabase or from the MCE_R response spectrum by looking up the ordinates corresponding to periods of 0.2 secs and 1.0 secs respectively.

The BSE-1N spectral accelerations, adjusted for site class effects, at short periods (S_{DS}) and at 1-second period (S_{D1}) must be determined as 2/3 of S_{MS} and S_{M1} , respectively. The design response spectrum for BSE-1N ground shall be obtained by multiplying the ordinates of the Multi-Period MCE_R response spectrum by 2/3.

B-16.1.1 Site Class Definition.

ASCE 7-22 Section 20.2 applies as written.

[C] B-16.1.1 – Site Class Definition.

Note that Site Class definitions have changed in ASCE 7-22. There are now nine site classes instead of six, site class BC, CD, and DE having been added to A, B, C, D, E, and F. Also the distinction among the site classes is now solely based on shear wave velocity. Standard penetration resistance or undrained shear strength can no longer be the basis of such distinction.

If S_s and S_1 values are required, they can be obtained from the MCE_R response spectrum from Site Class BC by looking up the ordinates corresponding to periods of 0.2 sec and 1.0 sec respectively. Alternatively they can be obtained directly from USGS Seismic Hazard Geodatabase.

B-16.2 Site-specific Response Analysis for Determining Ground Motion Accelerations.

B-16.2.1 Site Response Analysis

ASCE 7-22 Section 21.1 applies.

B-16.2.2 MCE_R Ground Motion Hazard Analysis.

ASCE 7-22 Section 21.2 applies.

B-17 EARTHQUAKE LOADS – CRITERIA SECTION.

B-17.1 Structural Design Criteria.

Each structure must be assigned a Seismic Design Category in accordance with 2024 IBC Section 1613.2.5/ASCE 7-22 Section 11.6, for use with required structural design and construction provisions. Each structure must be provided with complete lateral and vertical force-resisting systems capable of providing adequate strength, stiffness, and energy dissipation capacity to withstand the earthquake ground motions determined in accordance with Section B-16 within the prescribed performance objectives of Section B-18. In addition, each structure must be designed to accommodate the architectural, mechanical, and electrical component requirements of Section B-22. Ground motions must be assumed to occur along any horizontal direction of a structure. A continuous load path, or paths, with adequate strength and stiffness to transfer forces induced by the earthquake ground motions from the points of application to the final point of resistance must be provided.

B-17.2 Importance Factors.

The seismic importance factor, I_e , is not used. The component seismic importance factor, I_p , used in Section B-22, must be the value specified in Sections B-22.4.4.

B-17.3 Site Limitations.

A structure assigned to RC IV must not be sited where there is a known potential for an active fault to cause rupture of the ground surface at the structure. An *active fault* is defined in ASCE 7-22 as follows: A fault determined to be active by the Authority Having Jurisdiction from properly substantiated data (e.g., most recent mapping of active faults by the US Geological Survey).

[C] B-16.5 – Site Limitations.

In UFC 3-301-01, Change 1, 2 October 2023 (the previous version of this UFC), an active fault was defined as a fault for which there is an average historic slip rate of 1 mm or more per year and for which there is geographic evidence of seismic activity in Holocene times (the most recent 11,000 years). This definition dates back to the 2000 IBC.

B-17.4 Building Configuration.

The requirements of ASCE 7-22 Sections 12.3.1 [Diaphragm Flexibility], 12.3.2 [Irregular and Regular Classification], and 12.3.3 [Limitations and Additional Requirements for Systems with Structural Irregularities] do not apply to facilities designed using the provisions of this Chapter.

B-17.5 Analysis Procedures.

B-17.5.1 Nonlinear Analysis.

The Alternate RC IV analysis procedure of this Appendix may be used in lieu of the Equivalent Lateral Force or Modal Response Spectrum Analysis procedures that would generally be used to comply with the 2024 IBC and Chapter 2 of this UFC. For this alternate procedure, a nonlinear structural analysis must be performed. The analysis may use either the Nonlinear Static Procedure (NSP) or the Nonlinear Dynamic Procedure (NDP).

B-17.5.1.1 Nonlinear Static Procedure.

The NSP is permitted for structures not exceeding 6 stories in height and having a fundamental period, T , not greater than $3.5T_s$, where T_s is determined in accordance with ASCE 7-22 Section 11.4.6. Application of the NSP needs to comply with the requirements of *Resource Paper 2 of FEMA P-750, NEHRP Recommended Provisions for Seismic Regulations for New Buildings and Other Structures, 2009 Edition, Part 3, Resource Papers (RP) on Special Topics in Seismic Design, subject to the modifications below*. In applying the NSP, the user may employ the references cited in Resource Paper 2 of FEMA P-750. Further information on NSP may be found in *FEMA P-750, NEHRP Recommended Provisions for Seismic Regulations for New Buildings and Other*

Structures, 2009 Edition, Part 2, Commentary and in NEHRP Seismic Design Technical Brief No. 4, *Nonlinear Structural Analysis for Seismic Design*, NIST GCR 10-917-5. The following should be noted:

1. To apply the FEMA P-750 NSP, the design earthquake ground motions and associated spectral accelerations must be as specified herein (MCE_R and BSE-1N), and not the design ground motions defined in FEMA P-750.
2. A target displacement must be separately determined for each of the MCE_R and BSE-1N spectra.
3. The structure as a whole and each of the elements of the lateral force-resisting system and its connections must be evaluated for their adequacy to provide Immediate Occupancy Performance at the BSE-1N target displacement and to provide Life Safety Performance at the MCE_R target displacement.
4. P-Delta effects must be included in the development of the backbone curves (see Section 2.4 of NIST GCR 10-917-5 NEHRP Seismic Design Technical Brief No 4).
5. Multidirectional and concurrent seismic effects must be included as defined in Section 7.2.5 of ASCE/SEI 41-17.
6. The following modifications must be made to Resource Paper 2 of FEMA P-750
 - a. Replace references to ASCE 41-06 w/Supplement 1 with ASCE/SEI 41-17.
 - b. Replace references to Section 3.3.3 of ASCE 41-06 w/Supplement 1 with Section 7.4.3 of ASCE/SEI 41-17.
 - c. Replace references to Section 3.3.3.3.2 of ASCE 41-06 w/Supplement 1 with Section 7.4.3.3.2 of ASCE/SEI 41-17.
 - d. Replace reference to Equation 3-16 of ASCE/SEI 41-06 w/Supplement 1 with Equation 7-32 of ASCE/SEI 41-17 and replace μ_{max} in Equation 7-32 of ASCE/SEI 41-17 with R_{max} .

B-17.5.1.2 Nonlinear Dynamic Procedure.

Application of the NDP needs to comply with the requirements of ASCE 7-22 Chapter 16.

B-17.5.2 Site Ground Motions.

Two characteristic ground motions must be required for the design of facilities using this procedure:

1. For the LS performance level, the MCE_R ground motion must be used. For the NSP, spectral response accelerations must be determined using the procedures of Section B-16.1 or Section B-16.2. For the NDP, MCE_R ground motions must be determined using procedures prescribed in ASCE 7-22 Section 16.2.

2. For the IO performance level, the BSE-1N ground motion must be used. For the NSP, spectral response accelerations must be determined using the procedures of Section B-16.1 or Section B-16.2. For the NDP, BSE-1N ground motions must be determined using procedures prescribed in ASCE 7-22 Section 16.2.

B-18 EARTHQUAKE LOADS – MINIMUM DESIGN LATERAL FORCE AND RELATED EFFECTS.

B-18.1 Seismic Load Effect, E .

When the NSP is used, the seismic load effect, E , for use in the load combinations of Section B-5.2 must be determined from ASCE 7-22 Section 12.4. In the application of ASCE 7-22 Section 12.4, the term S_{DS} must be interpreted as S_{MS} for the LS performance level. When the NDP is used, the seismic load effect, E , is simply the response determined from the dynamic analysis. The redundancy coefficient, ρ , must be taken as 1.0.

Exceptions:

1. Where these provisions require consideration of structural overstrength (see ASCE 7-22 Section 12.4.3), the values of member forces, Q_E , obtained from NSP analysis at the peak (maximum base shear) of the NSP pushover curve must be used in place of the quantity E_{mh} .
2. Where these provisions require consideration of structural overstrength (see ASCE 7-22 Section 12.4.3), the values of member forces, Q_E , obtained from NDP analysis at the maximum base shear found in the analysis using any of the ground motion records must be used in place of the quantity E_{mh} .

B-18.2 Redundancy.

ASCE 7-22 Section 12.3.4 does not apply to facilities designed using the provisions of this Chapter.

B-18.3 Deflection and Drift Limits.

B-18.3.1 Allowable Story Drift.

Because the Alternate Design Procedure is a nonlinear performance-based design approach, specific target drift limits are not set for designs.

B-18.3.1.1 Life Safety Performance Level.

The LS performance level must be achieved for MCE_R ground shaking. At the LS performance level, structural members may be damaged, but they retain a margin of safety of at least 1.5 against the onset of loss of gravity load carrying capacity. Some residual global structural strength and stiffness remain at the maximum lateral

displacement in all stories. No out-of-plane wall failures occur. Partitions may be damaged, and the building may be beyond economical repair. Some permanent (inelastic) drift may occur. While inelastic behavior is permitted, member strength degradation needs to be limited in primary structural members (residual strength cannot be less than 80% of peak strength). Primary structural elements are those that are required to provide the building with an ability to resist collapse when ground motion-induced seismic forces are generated. For secondary structural elements (those that are not primary elements), strength degradation to levels below the nominal yield strength is permitted. Not more than 20% of the total strength or initial stiffness of a structure can be assumed to be provided by secondary elements. The LS performance objective needs to be verified by analysis - either the NSP or the NDP. The LS acceptance criteria contained in ASCE 41-17 must be used to demonstrate acceptable performance (see ASCE 41-17 Table 2-3). Alternatively, acceptance criteria can be developed by the designer and approved by the design review panel (see Section B-1.2).

B-18.3.1.2 Immediate Occupancy Performance Level.

The IO performance level must be achieved for BSE-1N ground shaking. At the IO performance level, a building remains safe to occupy, essentially retaining pre-earthquake design strength and stiffness and nonstructural elements retain position and are operational. Minor cracking of facades, ceilings, and structural elements may occur. Significant permanent (inelastic) drift does not occur. The structural system for the building remains “essentially” elastic. Any inelastic behavior does not change the basic structural response and does not present any risk of local failures. Member deformations are not permitted to exceed 125% of deformations at nominal member yield strengths. No member strength degradation is permitted, regardless of deformation. The IO performance objective needs to be verified by analysis, either the NSP or the NDP. The IO acceptance criteria contained in ASCE 41-17 must be used to demonstrate acceptable performance (see ASCE 41-17 Table 2-3). Alternatively, appropriate acceptance criteria can be developed by the designer and approved by the design review panel (see Section B-1.2).

B-18.3.2 Drift Determination and P-Delta Effects.

B-18.3.2.1 Drift and Deflection Determination for Nonlinear Static Procedure.

The design story drifts, Δ_S and Δ_M must be taken as the values obtained for each story at the target displacements for the BSE-1N and MCE_R, respectively.

B-18.3.2.2 Drift and Deflection Determination for Nonlinear Dynamic Procedure.

Transient as well as residual story drifts must be determined in accordance with ASCE 7-22 Sections 16.4.1.2 and 16.4.1.3, respectively.

B-18.3.2.3 P-Delta Effects for Nonlinear Static Procedure and Nonlinear Dynamic Procedure.

P-Delta ($P-\Delta$) effects must be incorporated in all lateral load analyses.

B-18.4 Seismic Force-resisting Systems.

B-18.4.1 Permitted Seismic Force-resisting Systems.

Table B-1, Permitted Systems for RC IV Buildings Designed Using Alternate Analysis Procedure, must replace ASCE 7-22 Table 12.2-1 and Table 3-1 of this UFC. Table B-1 must be used to determine whether a seismic force-resisting system is permitted. Table B-1 also lists building height limitations for the permitted systems. Seismic force-resisting systems that are not listed in Table B-1 may be permitted if analytical and test data are submitted that establish the dynamic characteristics and demonstrate the lateral force resistance and energy dissipation capacity to be equivalent to those of the structural systems listed in the table. Such exceptions may be authorized when permission is granted by the design review panel (see Section B-1.2).

B-18.4.2 Structural Design Requirements.

B-18.4.2.1 Dual Systems.

ASCE 7-22 Section 12.2.5.1 applies.

B-18.4.2.2 Combinations of Framing Systems.

Different seismic force-resisting systems are permitted along the two orthogonal axes of a building structure, so long as both systems comply with the provisions of this Chapter.

B-18.4.2.3 Interaction Effects.

Moment-resisting frames that are enclosed or adjoined by more rigid elements that are not considered to be part of the seismic force-resisting system must be designed so that the action or failure of those rigid elements will not impair the vertical load-carrying and seismic force-resisting capability of the frame. The design needs to provide for the effect of these rigid elements on the structural system at structural deformations corresponding to the design story drift at the target displacement, as determined by analysis.

B-18.4.2.4 Deformational Compatibility.

For components that are not included in the seismic force-resisting system, ensure that ductile detailing requirements are provided such that the vertical load-carrying capacity of these components is not compromised by induced moments and shears resulting from the design story drift.

For structures assigned to Seismic Design Category D, E, or F, reinforced concrete frame members not designed as part of the seismic force-resisting system must comply with ACI 318 *Building Code Requirements for Structural Concrete*, Section 18.14.

B-18.4.3 Response Modification (R), System Overstrength (Ω_0), Deflection Amplification (C_d) Factors.

Because only the NDP or the NSP are permitted for the alternate design of RC IV structures the factors R , C_d , and Ω_0 are not required.

B-18.4.4 Member Strength.

The load combination requirements of Sections B-5.1 and B-5.2 must be satisfied. Horizontal seismic load effects must be determined in accordance with Section B-18.1.

B-19 EARTHQUAKE LOADS, SOIL-STRUCTURE INTERACTION EFFECTS.

B-19.1 Analysis Procedure.

When these effects are considered, the provisions of ASCE 7-22 Chapter 19 apply.

B-20 SEISMIC DESIGN AND STRUCTURAL MEMBER LOAD EFFECTS.

B-20.1 Structural Member Load Effects.

The provisions of ASCE 7-22 Chapter 12, as modified by Chapter 3 of this UFC, apply.

B-20.2 Structural Integrity.

The provisions of 2024 IBC Section 1616 apply.

B-20.3 Soils and Foundations.

The provisions of 2024 IBC Chapter 18 apply.

B-21 SEISMIC DESIGN REQUIREMENTS FOR NONSTRUCTURAL COMPONENTS.

B-21.1 Component Design.

The provisions of ASCE 7-22 Chapter 13, as modified by Chapter 3, apply, except as noted in the following paragraphs. Appendix C provides supplementary guidance on design and analysis of some architectural, mechanical, and electrical components.

B-21.2 Performance Objectives.

The design procedure presented in this Appendix includes two overall performance objectives that influence the requirements for architectural, mechanical, and electrical components. First, the design must provide Hazards Reduced (HR) performance for the MCE_R . Second, the design must provide Operational (OP) performance for BSE-1N ground motions.

B-21.2.1 Hazards Reduced Performance Level for Nonstructural Components.

This performance level is defined as the post-earthquake damage state in which nonstructural components are damaged and could potentially create falling hazards. High-hazard nonstructural components identified in Chapter 13, Table 13-1 of ASCE 41-17 are secured to prevent falling into areas of public assembly because falling hazards from those components could pose a risk to life-safety of many people. Preservation of egress, protection of fire suppression systems, and similar life-safety issues are not addressed in this Nonstructural Performance Level.

B-21.2.2 Operational Performance Level for Nonstructural Components.

This performance level is defined as the post-earthquake damage state in which the nonstructural components are able to provide the functions they provided in the building before the earthquake. Nonstructural components in compliance with the acceptance criteria of ASCE 41-17 for Operational Nonstructural Performance and Risk Category IV nonstructural components are expected to achieve this post-earthquake state.

B-21.3 Modification of ASCE 7-22 for Hazards Reduced Design.

B-21.3.1 Ground Motion Parameters for Determination of Hazards Reduced Seismic Forces.

In the application of ASCE 7-22 Section 13.3.1, seismic forces must be determined for the MCE_R ground motion parameters.

B-21.3.2 Nonlinear Static Procedure.

In the application of ASCE 7-22 Section 13.3.1, seismic forces on components, when NSP is used, must be based on ASCE 7-22 Equations 13.3-1 through 13.3-3. The quantity S_{MS} must be substituted for the term S_{DS} found in the equations. In the application of ASCE 7-22 Section 13.3.2, the response of the building to the MCE_R ground motion must be used.

B-21.3.3 Nonlinear Dynamic Procedure.

In the application of ASCE 7-22 Section 13.3.1, seismic forces on components, when NDP is used, must be based on ASCE 7-22 Equation 13.3-7. The term a_i is the maximum acceleration at the level of the component under consideration, as determined from the dynamic analysis. In the application of ASCE 7-22 Section 13.3.2, the response of the building to the MCE_R ground motion must be used.

B-21.4 Modification of ASCE 7-22 for Operational Design.

B-21.4.1 Ground Motion Parameters for Determination of IO Seismic Forces.

In the application of ASCE 7-22 Section 13.3.1, seismic forces must be determined for the BSE-1N ground motion parameters.

B-21.4.2 Nonlinear Static Procedure.

In the application of ASCE 7-22 Section 13.3.1, seismic forces on components, where NSP is used, must be based on ASCE 7-22 Equations 13.3-1 through 13.3-3. In the application of ASCE 7-22 Section 13.3.2, the response of the building to the BSE-1N ground motion must be used.

B-21.4.3 Nonlinear Dynamic Procedure.

In the application of ASCE 7-22 Section 13.3.1, seismic forces on components, where NDP is used, must be based on ASCE 7-22 Equation 13.3-7. The term a_i is the maximum acceleration at the level of the component under consideration, as determined from the dynamic analysis. In the application of ASCE 7-22 Section 13.3.2, the response of the building to the BSE-1N ground motion must be used.

B-21.4.4 Component Importance Factors.

The component importance factor, I_p , is required for force calculations in ASCE 7-22 Section 13.3.1. I_p must be as given in ASCE 7-22 Section 13.1.3.

¹ Any system that is restricted by this table may be permitted if it is approved by the design review panel (see Section B-1.2).

² See Table 3-1 for detailing references for seismic force-resisting systems.

³ Steel ordinary concentrically braced frames are permitted in single-story buildings, up to a structural height, h_n , of 60 ft, where the dead load of the roof does not exceed 20 psf, and in penthouse structures.

⁴ Ordinary moment frames may be used in lieu of intermediate moment frames for Seismic Design Category B or C.

⁵ See ASCE 7-22 Section 12.2.5.7 for limitations on structures assigned to Seismic Design Category D, E, or F.

⁶ See ASCE 7-22 Section 12.2.5.6 for limitations on structures assigned to Seismic Design Category D, E, or F.

⁷ Structural height, h_n , shall not be less than 60 ft (18.3m).

APPENDIX C GUIDANCE FOR SEISMIC DESIGN OF NONSTRUCTURAL COMPONENTS

C-1 INTRODUCTION.

This Appendix defines architectural, mechanical, and electrical components, discusses their participation and importance in relation to the seismic design of the structural system, and provides guidance for their design to resist damage from earthquake-induced forces and displacements. The fundamental principles and underlying requirements of this Appendix are that the design of these components for buildings in Risk Categories (RCs) I, II, and III should be such that they will not collapse and cause personal injury due to the accelerations and displacements caused by severe earthquakes, and that they should withstand more frequent but less severe earthquakes without excessive damage and economic loss. In contrast, designated components in RC IV buildings, are required to remain operational following a design earthquake (BSE-1N).

C-1.1 Design Criteria.

2024 IBC Section 1613, as modified by Chapter 2 of this UFC, governs the seismic design of architectural, mechanical, and electrical components. 2024 IBC Section 1613 references Chapter 13 of ASCE 7-22. Because ASCE 7-22 is the primary source of design requirements for these components, this Appendix cites ASCE 7-22 provisions and expands on them as appropriate.

C-1.2 Walk-down Inspections and Seismic Mitigation for Buildings in Risk Categories IV.

C-1.2.1 General Guidance.

Section 1705.13.6 of UFC 3-301-01 requires that an initial *walk-down* inspection of new RC IV buildings be performed. A walk-down inspection is a visual inspection of a building to identify possible seismic vulnerabilities of its architectural, mechanical, and electrical components. Inspections should include investigating adequacy of component load paths, anchorage and bracing, and components' abilities to accommodate differential motions with respect to supporting building structure. The walk-down inspector should become familiar with the design earthquake motions for the site, structural configuration of the building, building drawings, and documentation of all previous walk-down inspections. Inspectors should document all observations with photographs, schematic drawings, and narrative discussions of apparent vulnerabilities. Inspection reports normally do not include detailed assessments of component vulnerabilities, but they may recommend further detailed assessments. Inspectors should also define mitigation recommendations in inspection reports. Prior to building commissioning, the Authority Having Jurisdiction (AHJ) should ensure seismic mitigation recommendations are fully implemented. An example of a walk-down inspection of Madigan Army Medical Center at Fort Lewis, WA, may be found in

USACERL Technical Report 98/34, *Seismic Mitigation for Equipment at Army Medical Centers*.

C-1.2.2 Periodic Post-commissioning Walk-down Inspections.

In addition to initial walk-down inspections performed at building commissioning, periodic post- construction walk-down inspections should be conducted in RC IV buildings by installation personnel, as part of routine operations and maintenance. For RC IV buildings, such inspections should be conducted at least every second year following building commissioning, or, for affected systems, when any change to architectural, mechanical, or electrical systems occurs.

C-2 ARCHITECTURAL COMPONENTS.

C-2.1 General.

Reference should be made to ASCE 7-22 Section 13.5, Architectural Components.

Architectural components addressed in ASCE 7-22 Chapter 13 are listed in ASCE 7-22 Table 13.5-1. These components are called “architectural” because they are not part of the vertical or lateral load-resisting systems of a building, or part of the mechanical or electrical systems. Although they are usually shown on architectural drawings, they often have a structural aspect and can affect the response of a building to earthquake ground motions. Architects should consult with structural, mechanical, and electrical engineers, as appropriate, when dealing with these elements. The structural engineer must review architectural (as well as mechanical and electrical) component anchorage details, to ensure compliance with anchorage requirements. During this review, the structural engineer must also identify installed architectural (as well as mechanical and electrical) components that may adversely affect the performance of the structural system.

C-2.2 Typical Architectural Components.

Examples of architectural components that have a structural aspect requiring special attention follow.

C-2.2.1 Nonstructural Walls.

A wall is considered architectural or nonstructural when it is not designed to resist transient interior (lateral) air pressure of more than 5psf or superimposed gravity loads beyond the threshold values given in the definition for bearing walls in 2024 IBC Section 202 and ASCE 7-22 Section 11.2. To ensure that nonstructural walls do not resist lateral forces, they should either be disconnected (i.e., isolated) from the building structure at the top and the ends of the wall or be very flexible (in-plane) relative to the structural walls and frames resisting lateral forces. An isolated wall must be capable of acting as a cantilever from the floor or be braced to resist its own out-of-plane motions

and loads, without interacting with the lateral force-resisting system. Such interaction may be detrimental to the wall or the lateral force-resisting system or both.

C-2.2.2 Curtain Walls and Filler Walls.

A curtain wall is an exterior wall, often constructed of masonry, that lies outside of and usually conceals the structural frame of a building. A filler wall is an infill, usually constructed of masonry, within the structural members of a frame. These walls are often considered architectural in nature if they are designed and detailed by the architect. However, they can act as shear (structural) walls. If they are connected to the frame, they will be subjected to the deflections of the frame and will participate with the frame in resisting lateral forces. Curtain walls and infill walls in buildings governed by this document should be designed so they do not restrict the deformations of the structural framing under lateral loads (i.e., they are isolated from building lateral deformations). Lateral supports and bracing for these walls should be provided as prescribed in this Appendix.

C-2.2.3 Partial Infill Walls.

A partial infill wall is one that has a strip of window between the top of the solid infill and the bottom of the floor above, or has a vertical strip of window between one or both ends of the infill and a column. Such walls require special treatment. If they are not properly isolated from the structural system, they will act as shear walls. The wall with windows along the top is of particular concern because of its potential effect on the adjacent columns. The columns are fully braced where there is an adjacent infill, but are unbraced in the zone between the windows. The upper, unbraced part of the column is a “short column,” and its greater rigidity (compared with the other, longer unbraced columns in the system) must be considered in structural design. Short columns are very susceptible to shear failure in earthquakes. Figure C-1 shows a partial infill wall, with short columns on either side of the infill, which should be avoided. All infills in buildings governed by this document should be considered to be nonstructural components, and should be designed so they do not restrict the deformation of the structural framing under lateral loads. In this instance, the partial infill should be sufficiently isolated from the adjacent frame elements to permit those elements to deform in flexure as designed.

C-2.2.4 Precast Panels.

Exterior walls that consist of precast panels attached to the building frame are addressed in a different way. The general layout and wall section for wall panels is usually shown on architectural drawings, while structural details for the support of the panels are usually shown on structural drawings. It is common for the detailed structural design of the precast panels to be delegated to a specialty engineer engaged by the General Contractor or by the precast concrete panel subcontractor. This is done because the details of design may vary depending on the manufacturing methods and facilities of the panel manufacturer. The specialty engineer is engaged to incorporate

those considerations as well as means and methods of construction that the project structural engineer excludes from the scope of work. The structural engineer must review this design as needed to verify that the application of loads and the configuration of the connection details are compatible with the design of the supporting structure. In such cases, structural drawings should include design criteria and representative details in order to show what is expected. The design criteria should include the required design forces and frame deflections that must be accommodated by the panels and their connections. Particular attention should be given to the effects of deflections of the frame members supporting precast panels, to assure that appropriate reaction forces and deflections are considered. Panels with more than two attachment points between their bottom edge and the supporting frame should be avoided. Further guidance can be found in *Architectural Precast Concrete*, 3rd Edition (PCI MNL-122-07), published by the Precast/Prestressed Concrete Institute (PCI).

Figure C-1. Partial Infill Masonry Wall between Two Concrete Columns, Causing Adverse “Short Column” Effect

C-2.2.5 Masonry Veneer.

Reference should be made to *Building Code Requirements for Masonry Structures* (TMS 402-22). A masonry veneer is defined as a masonry wythe that provides the exterior finish of a wall system and transfers out-of-plane load directly to a backing, but is not considered to add load-resisting capacity to the wall system. A masonry veneer may be anchored or adhered. An anchored veneer is defined as a masonry veneer secured to and supported laterally by the backing through anchors and supported vertically by the foundation or other structural elements. An adhered veneer is defined as a masonry veneer secured to and supported by the backing through adhesion. Chapter 13 of TMS 402 provides requirements for design and detailing of anchored masonry veneer and adhered masonry veneer. The design of anchored veneer is

addressed in Section 13.2 of TMS 402, while the design of adhered veneer is addressed in Section 13.3 of the same document.

C-2.2.6 Rigid Partition Walls.

Rigid partition walls are generally nonstructural masonry walls. Such walls should be isolated, so they are not called upon to resist in-plane lateral forces to which they are subjected, based on relative rigidities. Typical details for isolating these walls are shown in Figure C-2. These walls should be designed for the prescribed forces normal to their plane.

Figure C-2. Typical Details for Isolation of Rigid Partition Walls

C-2.2.7 Nonrigid Partition Walls.

Nonrigid partition walls are generally nonstructural partitions, such as stud and drywall, stud and plaster, and movable partitions. When these partitions are constructed according to standard recommended practice, they are assumed to be able to withstand design in-plane drift of only 0.005 times the story height (1/16 in./ft [5 mm/m] of story height) without damage. This is much less than the most restrictive allowable story drift in ASCE 7-22 Table 12.12-1. Therefore, damage to these partitions should be expected in the design earthquake if they are anchored to the structure in the in-plane direction. For RC IV, these partition walls should be isolated from in-plane building motions at the tops and sides of partitions if drifts exceeding 0.005 times the story height are anticipated in the design earthquake. Partition walls should be designed for the prescribed seismic force acting normal to flat surfaces. However, the wind or the usual 5 pounds per square foot partition load (2024 IBC Section 1607.16) will usually govern.

Economic comparison between potential damage and costs of isolation should be considered. For partitions that are not isolated, a decision has to be made for each project as to the contribution, if any, such partitions will make to damping and response of the structure, and the effect of seismic forces parallel to (in-plane with) the partition resulting from the structural system as a whole. Usually, it may be assumed that this type of a partition is subject to future changes in floor layout location. The structural role of partitions may be controlled by limiting the height of partitions and by varying the method of support.

C-2.2.8 Suspended Ceilings.

Requirements for suspended ceilings are provided in ASCE 7-22 Section 13.5.6, as modified by Chapter 3. Useful guidance is available in ICC-ES AC 308 *Acceptance Criteria for Suspended Ceiling Framing Systems*, issued by the International Code Council Evaluation Service (ICC-ES) in February 2024.

C-3 MECHANICAL AND ELECTRICAL COMPONENTS.

C-3.1 Component Support.

Reference should be made to ASCE 7-22 Section 13.6.4 Component Supports.

C-3.1.1 Base-mounted Equipment in RC IV.

Floor or pad-mounted mission-critical equipment installed in RC IV buildings assigned to SDC D, E, or F should use cast-in-place anchor bolts to anchor them. Alternatively, post-installed anchors are permitted to be used provided they are qualified for earthquake loading in accordance with ACI 308.2, *Qualification of Post-Installed Mechanical Anchors in Concrete*, and ACI 308.4, *Acceptance Criteria for Qualification of Post-Installed Adhesive Anchors in Concrete*, as applicable. For this equipment, two nuts should be provided on each bolt, and anchor bolts should conform to ASTM F1554-20, *Standard Specification for Anchor Bolts, Steel, 36, 55, and 105-ksi Yield*

Strength. Cast-in-place anchor bolts should have an embedded straight length equal to at least 12 times the nominal bolt diameter. Anchor bolts that exceed the depth of equipment foundation piers or pads should either extend into the concrete floor, or the foundation should be increased in depth to accommodate the bolt lengths. Figure C-3 illustrates typical base anchorage and restraint for equipment.

Figure C-3. Typical Seismic Restraints for Floor-mounted Equipment

C-3.1.2 Suspended Equipment.

Seismic bracing for suspended equipment may use the bracing recommendations and details in ANSI/SMACNA 001-2008, *Seismic Restraint Manual: Guidelines for Mechanical Systems*, 3rd Edition. Trapeze-type hangers should be secured with not less than two bolts. Figure C-4 shows typical seismic restraints for suspended equipment.

Figure C-4. Typical Seismic Restraints for Suspended Equipment

SUSPENDED EQUIPMENT

SUSPENDED EQUIPMENT WITH VIBRATION MOUNT

C-3.1.3 Supports and Attachments for Piping.

Seismic supports required in accordance with ASCE 7-22-Section 13.6.7, Distribution Systems: Piping and Tubing Systems, should be designed in accordance with the following guidance. This piping is not constructed in accordance with ASME B31 or NFPA 13.

C-3.1.3.1 General.

The provisions of this section apply to all risers and riser connections; all horizontal pipes and attached valves; all connections and brackets for pipes; flexible couplings and expansion joints; and spreaders. The following general guidance applies to these elements:

1. For seismic analysis of horizontal pipes, the equivalent static force should be considered to act concurrently with the full dead load of the pipe, including contents.
2. All connections and brackets for pipes should be designed to resist concurrent dead and equivalent static forces. Seismic forces should be determined from ASCE 7-22 Section 13.3.1. Supports should be provided at all pipe joints unless continuity is maintained. Figure C-5 provides acceptable sway bracing details.
3. Flexible couplings should be provided at the bottoms of risers for pipes larger than 3.5 in. (89 mm) in diameter. Flexible couplings and expansion joints should be braced laterally and longitudinally unless such bracing would interfere with the action of the couplings or joints. When pipes enter buildings, flexible couplings should be provided to allow for relative movement between the soil and the building.
4. Spreader should be provided at appropriate intervals to separate adjacent pipelines unless pipe spans and clear distances between pipes are sufficient to prevent contact between the pipes during an earthquake.

C-3.1.3.2 Rigid versus Flexible Piping Systems.

Piping systems should be considered either rigid or flexible. The dynamic response of rigid piping systems is assumed to be decoupled from the building's amplified response, so that the component resonance ductility factor factor, C_{AR} , is set to 1.0. It is assumed that flexible pipes may couple with and further amplify building motion. Designers are encouraged to use high-deformability pipe systems that may permit longer pipe support spacing. It should be noted that when high-deformability pipe systems, which have the larger R_{po} values, are used (e.g., welded steel pipe systems), F_p , may be limited by the minimum value set forth by ASCE 7-22 Equation 13.3-3. Forces based on ASCE 7-22 Equation 13.3-3 may also govern for pipes installed in lower levels of a building.

Figure C-5. Acceptable Seismic Details for Pipe Sway Bracing

C-3.1.3.2.1 Rigid Piping System.

A piping system is assumed rigid if its maximum period of vibration is no more than 0.06 second (ASCE 7-22-Section 11.2 definition for Component, rigid). ASCE 7-16 Table 13.6-1 Footnote 1 used to indicate that a_p equals 1.0 for rigid pipes, where the support motions are not amplified. Rigid and rigidly attached pipes should be designed in accordance with ASCE 7-22 Equation 13.3-1, where W_p is the weight of the pipes, their contents, and attachments. Forces should be distributed in proportion to the total weight of pipes, contents, and attachments.

Tables C-1, C-2, and C-3 may be used to determine allowable span-diameter relationships for rigid pipes; standard (40S) pipe; extra strong (80S) pipe; types K, L, and M copper tubing; and 85 red brass or SPS copper pipe in RC IV buildings. These tables are based on water-filled pipes with periods equal to 0.06 second. Figures C-6, C-7, and C-8 display support conditions for Tables C-1, C-2, and C-3, respectively. The relationship used to determine maximum pipe lengths, L , shown in the tables, that will result in rigid pipes having a maximum period of vibration of 0.06 seconds, is given in Equation C-1 (which is excerpted from the *Shock and Vibration Handbook*, 6th Edition, 2009):

$$L = \sqrt{C \pi T_a \sqrt{\frac{EI_g}{w}}}, \text{ in. or mm} \quad \text{(Equation C-1)}$$

where

C = period constant, equal to 0.50 for pinned-pinned pipes; 0.78 for fixed- pinned pipes; and 1.125 for fixed-fixed pipes

T_a = natural period of pipe in its fundamental mode, set equal to 0.06 second

E = modulus of elasticity of pipe, psi or MPa

I = moment of inertia of pipe, in⁴ or mm⁴

w = weight of pipe and contents per unit length, lb/in. or N/mm

Table C-1

C-3.1.3.2.2 Flexible Piping Systems.

Piping systems that do not comply with the rigidity requirements of Section C-3.1.3.2.1 (i.e., period less than or equal to 0.06 second) should be considered flexible (i.e., period greater than 0.06 second). Flexible piping systems should be designed for seismic forces with consideration given to both the dynamic properties of the piping system and the building or structure in which it is placed. In lieu of a more detailed analysis, equivalent static lateral force may be computed using ASCE 7-22 Equation 13.3-1, with $\left[\frac{C_{AR}}{R_{po}} \right] = 2.5$. The forces should be distributed in proportion to the total weight of pipes, contents, and attachments. If the weight of attachments is greater than 10% of pipe weight, attachments should be separately braced, or substantiating calculations should be required. If temperature stresses are appreciable, substantiating calculations should be required. The following guidance should also be followed for flexible pipe systems:

1. Separation between pipes should be a minimum of four times the calculated maximum displacement due to F_p , but not less than 4 in. (102 mm) clearance between parallel pipes, unless spreaders are provided.
2. Clearance from walls or rigid elements should be a minimum of three times the calculated displacement due to F_p , but not less than 3 in. (76 mm) clearance from rigid elements.
3. If the provisions of the above paragraphs appear to be too severe for an economical design, alternative methods based on rational and substantial analysis may be applied to flexible piping systems.
4. Acceptable seismic details for sway bracing are shown in Figure C-5.

C-3.2 Stacks (Exhaust) Associated with Buildings.

Reference should be made to ASCE 7-22 Section 13.6, as modified by Section 13.6.1 of Chapter 3 of this UFC, and ASCE 7-22 Chapter 15.

C-3.2.1 General.

Stacks are actually vertical beams with distributed mass and, as such, cannot be modeled accurately by single-mass systems. This design guidance applies to either cantilever or singly-guyed stacks attached to buildings. When a stack foundation is in contact with the ground and the adjacent building does not support the stack, it should be considered to be a nonbuilding structure (see ASCE 7-22 Chapter 15). This guidance is intended for stacks with a constant moment of inertia. Stacks having a slightly varying moment of inertia should be treated as having a uniform moment of inertia with a value equal to the average moment of inertia.

Stacks that extend more than 15 ft (4.6 m) above a rigid attachment to the supporting building should be designed according to the guidance for cantilever stacks presented in Section C-3.2.2 of this UFC. Stacks that extend less than 15 ft (4.6 m) should be designed for the equivalent static lateral force defined in ASCE 7-22 Section 13.3.1 using the C_{AR} and R_{po} values in ASCE 7-22 Table 13.6-1.

Stacks should be anchored to supporting buildings using long anchor bolts (where bolt length is at least 12 bolt diameters). Much more strain energy can be absorbed with long anchor bolts than with short ones. The use of long anchor bolts has been demonstrated to give stacks better seismic performance. A bond-breaker material should be used on the upper portion of the anchor bolt to ensure a length of unbonded bolt for strain energy absorption. Two nuts should be used on anchor bolts to provide an additional factor of safety.

C-3.2.2 Cantilever Stacks.

The fundamental period of a cantilever stack should be determined from the period coefficient (e.g., $C = 0.0909$) provided in Figure C-9, unless actually computed. The equation and the period coefficients, C , shown in Figure C-9 were derived from the *Shock and Vibration Handbook* (6th Edition, 2009). Dynamic response of ground-supported stacks may be calculated from the appropriate base shear equations for the Equivalent Lateral Force Procedure defined in ASCE 7-22 Section 12.8.

C-3.2.3 Guyed Stacks.

Analysis of guyed stacks depends on the relative rigidities of the cantilever component and the guy cable support system. If a cable is relatively rigid compared to the cantilever component, the stack should respond in a manner similar to the higher modes of vibration of a cantilever, with periods and mode shapes similar to those shown in Figure C-9. The fundamental period of vibration of the guyed system should be somewhere between the values for the fundamental and the appropriate higher mode of a similar cantilever stack. An illustration for a single guyed stack is shown in Figure C-10. Guyed stacks should be designed with rigid cables so that the true deflected shape is closer to that shown on the right side of Figure C-10. This requires pretensioning of guy cables to a minimum of 10 percent of stack seismic forces, F_p . Design for guyed stacks is beyond the scope of this document. However, some guidance may be found in TIA-222-I, *Structural Standard for Antenna Supporting Structures, Antennas and Small Wind Turbine Support Structures*, September 2023.

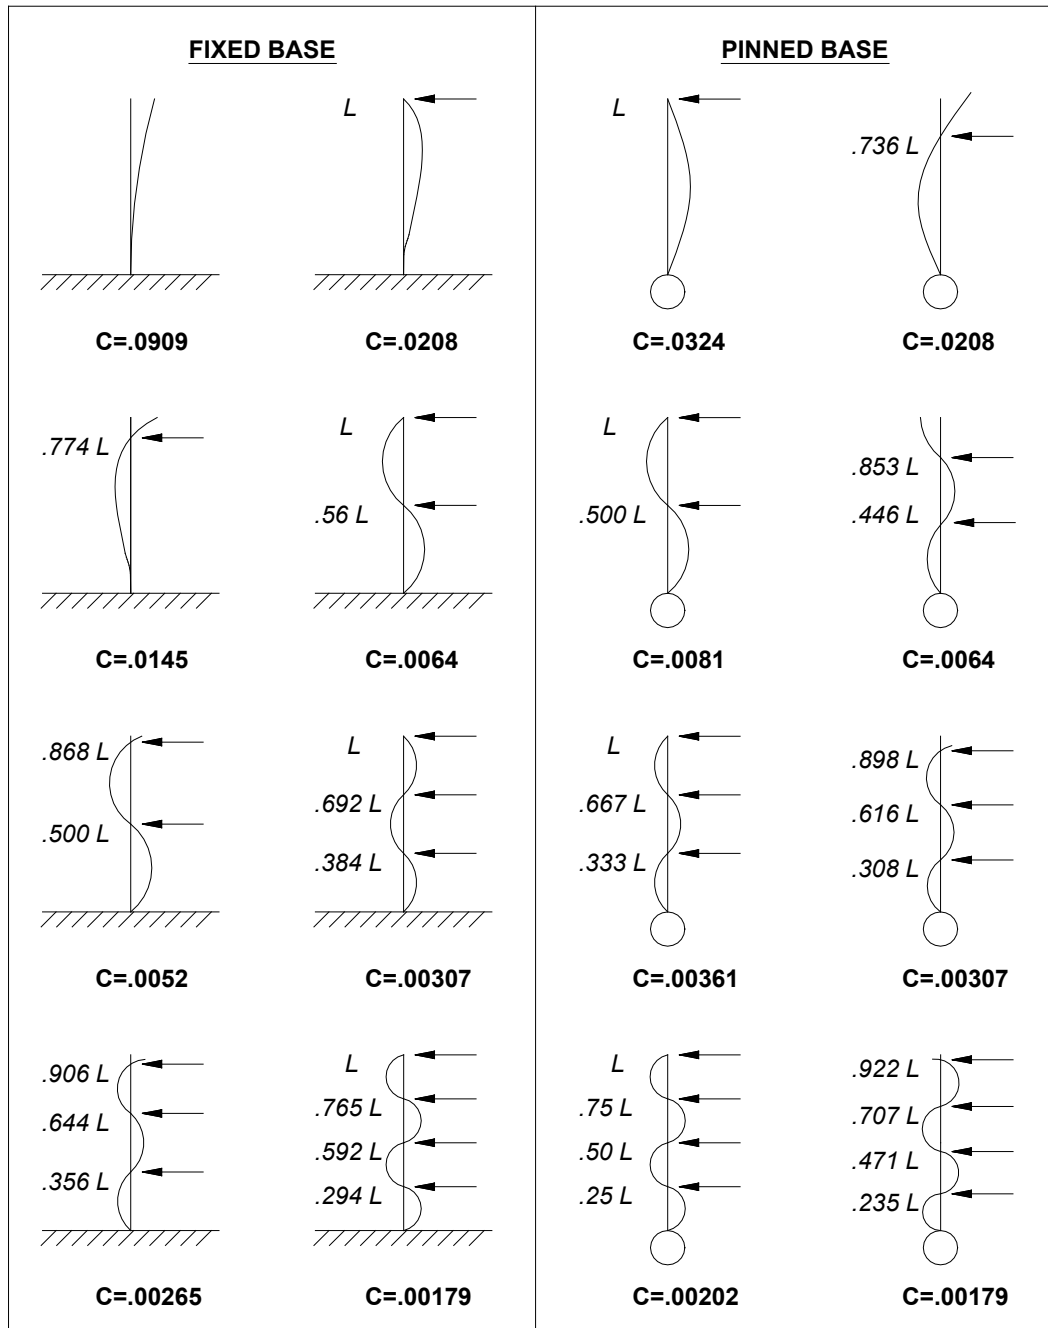

C-3.3 Elevators.

Reference should be made to ASCE 7-22 Section 13.6.11, Elevator and Escalator Design Requirements, as modified by Section 13.6.11.3 of Chapter 3 of this UFC.

C-3.3.1 General.

Elevator car and counterweight frames, roller guide assemblies, retainer plates, guide rails, and supporting brackets and framing (Figure C-11) should be designed in accordance with ASCE 7-22 Section 13.6.11. Lateral forces acting on guide rails should be assumed to be distributed one-third to top guide rollers and two-thirds to bottom guide rollers of elevator cars and counterweights. An elevator car and/or counterweight should be assumed to be located at its most adverse position in relation to its guide rails and support brackets. Horizontal deflections of guide rails should not exceed 1/2 in. (12.7 mm) between supports, and horizontal deflections of the brackets should not exceed 1/4 in. (6.4 mm).

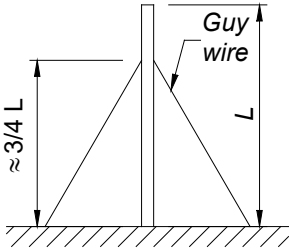

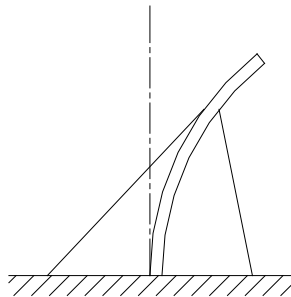

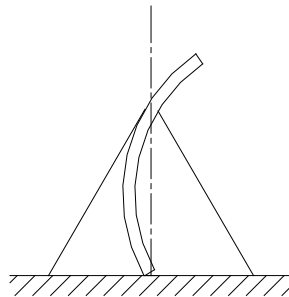

Figure C-9. Period Coefficients for Uniform Beams

$$T_a = C \sqrt{\frac{wL^4}{EI}}$$

T_a = Fundamental period (sec)
 w = Weight per unit length of beam (lb/in) (N/mm)
 L = Total beam length (in) (mm)
 I = Moment of inertia (in^4) (mm^4)
 E = Modulus of elasticity (psi) (MPa)
 C = Period constant

Figure C-10. Single Guyed Stacks

DESCRIPTION	DEFLECTED SHAPE	
	FLEXIBLE WIRE	RIGID WIRE
		

C-3.3.2 Retainer Plates.

In structures assigned to SDC D, E, and F, clearances between the machined faces of rail and retainer plates should not be more than 3/16 in. (4.8 mm), and the engagement of a rail should not be less than the dimension of its machined side face. When a car safety device attached to lower members of a car frame complies with lateral restraint requirements, a retainer plate is not required for the bottom of the car.

C-3.3.3 Counterweight Tie Brackets.

In structures assigned to SDC D, E, and F, the maximum spacing of counterweight rail tie brackets tied to a building structure should not exceed 16 ft (4.9 m). An intermediate spreader bracket, which is not required to be tied to a building structure, should be provided for tie brackets spaced greater than 10 ft (3.0 m), and two intermediate spreader brackets are required for tie brackets spaced greater than 14 ft (4.3 m).

C-3.3.4 Force Calculation.

Elevator machinery and equipment should be designed for $\left[\frac{C_{AR}}{R_{po}} \right] = 1.0$ in ASCE 7-22 Equation 13.3-1, when rigid and rigidly attached. Non-rigid or flexibly mounted equipment (which has a period greater than 0.06 second) should be designed with $\left[\frac{C_{AR}}{R_{po}} \right] = 2.5$.

Figure C-11. Elevator Details

C-3.4 Lighting Fixtures in Buildings

Reference should be made to ASCE 7-22 Sections 13.2.5 Testing Alternative for Seismic Capacity Determination, 13.5.6 Suspended Ceilings, 13.6.1 General, 13.6.2 Mechanical Components, 13.6.3 Electrical Components, and 13.6.4 Component Supports as modified by Chapter 3 of this UFC in the Sections 13.5.6, 13.6.1, 13.6.2, 13.6.3, and 13.6.4.

C-3.4.1 General.

Lighting fixtures, including their attachments and supports, in SDC C, D, E, and F buildings should conform to the following materials and construction requirements:

1. Fixture supports should use materials that are suitable for that purpose. Cast metal parts, other than those of malleable iron, and cast or rolled threads, should be subject to special investigation to ensure structural adequacy.
2. Loop and hook or swivel hanger assemblies for pendant fixtures should be fitted with restraining devices to hold their stems in the support position during earthquake motions. Pendant-supported fluorescent fixtures should also be provided with flexible hanger devices at their attachments to the fixture channel to preclude breaking of the support. Motions of swivels or hinged joints should not cause sharp bends in conductors or damage to insulation.
3. A supporting assembly that is intended to be mounted on an outlet box should be designed to accommodate mounting features on 4 in. (102 mm) boxes, 3 in. (76 mm) plaster rings, and fixture studs.
4. Each surface-mounted individual or continuous row of fluorescent fixtures should be attached to an earthquake-resisting ceiling support system. Support devices for attaching fixtures to suspended ceilings should be locking-type scissor clamps or full loop bands that will securely attach to the ceiling support. Fixtures attached to the underside of a structural slab should be properly anchored to the slab at each of their corners.
5. Each wall-mounted emergency light unit should be secured in a manner that will hold the unit in place during a seismic disturbance.

C-3.5 Bridges, Cranes, and Monorails.

Reference should be made to ASCE 7-22 Section 13.6 Mechanical and Electrical Component, as modified by Chapter 3 of this UFC in the Sections 13.6.14 Bridges, Cranes, and Monorails and 13.6.14.1 Bridges, Cranes, and Monorails for RC IV Buildings and 2024 IBC Section 1607.15.

C-3.5.1 General.

2024 IBC Section 1607.15 provides live load design guidance for cranes. Vertical restraints should be provided to resist crane uplift. Experience has shown that vertical ground motions can be amplified significantly in either crane bridges or crane rail support brackets that are cantilevered from columns. Analysis of cranes should consider their amplified response in the vertical direction, in addition to horizontal response. The criteria in Section 13.6.14 in Chapter 3 of this UFC specify C_{AR} of 1.5 and R_{po} of 1.5, resulting in $c \left[\frac{C_{AR}}{R_{po}} \right] = 1.0$ in the direction parallel to crane rails, because a crane bridge would almost certainly be flexible enough along its weak axis to have a natural period greater than 0.06 seconds. The C_{AR} factor is greater than 1.0 because, at large natural periods, a crane bridge can be expected to amplify ground and building motions. This factor has a value of 1.0 perpendicular to crane rails because the bridge would be loaded axially in this direction, resulting in a natural period that is less than 0.06 second. The crane bridge is considered to be rigid when loaded axially, so that it will not amplify ground or building motions. When a crane is not in the locked position, it is reasonable to assume that upper bound forces in the direction parallel to crane rails, between the wheels and the rails, cannot exceed a conservative estimate of the force that could be transmitted by friction between the brake wheels and rails.

APPENDIX D MECHANICAL AND ELECTRICAL COMPONENT CERTIFICATION

D-1 COMPONENT CERTIFICATION.

D-1.1 General.

The background to mechanical and electrical component certification is explained in *Special Seismic Certification of Nonstructural Components* (Tobolski, M., Structural Engineering and Design, 2011).

ASCE 7-22 Section 13.2 states that certification must be by analysis, testing or experience data. Mechanical and electrical equipment that must remain operable following the design earthquake ground motion must be certified based on shake table testing or experience data unless it can be shown that the component is inherently rugged by comparison with similar seismically qualified components (Section 13.2.3). ASCE 7-22 Section 13.2.3 Item 2 states that “Components with hazardous substances and assigned a component Importance Factor, I_p , of 1.5 in accordance with Section 13.1.3 shall be certified by the manufacturer as maintaining containment following the design earthquake ground motion by (a) analysis, (b) approved shake table testing in accordance with Section 13.2.6, or (c) experience data in accordance with Section 13.2.7.”

HCAI has issued a Policy Intent Notice (PIN) 55 on its Special Seismic Certification Preapproval (OSP) program. This program offers a means to obtain prequalification of product lines for special seismic certification. The details of this program can be found at https://hcai.ca.gov/wp-content/uploads/2022/08/PIN-55_Special-Seismic-Certification-Preapproval-OSP_080322_A-1.pdf. Lists of equipment that is pre-approved by HCAI can be found at <https://hcai.ca.gov/construction-finance/preapproval-programs/hcai-special-seismic-certification-preapproval-osp-by-category/>. The basis of HCAI preapproval always is shake table testing in compliance with ICC-ES AC156 and satisfaction of ICC-ES AC156 post-test acceptance criteria.

References in this appendix are made to ASCE 7-22 Section 13.2, General Design Requirements, and Chapter 3 of this UFC Section 13.2.3.

D-1.1.1 Analytical Certification.

Certification based on analysis, as noted in ASCE 7-22 Section 13.2.3 Item 3, requires a reliable and conservative understanding of the equipment configuration, including the mass distribution, strength, and stiffness of the various subcomponents. From this information, an analytical model may be developed that reliably and conservatively predicts the equipment dynamic response and potential controlling modes of failure. If such detailed information on the equipment or a basis for conservative estimates of these properties is not available, then methods other than analysis must be used. The use of analysis for active or energized components is not permitted (see ASCE 7-22 Section 13.2.3 Item 1). Examples of active designated seismic equipment include

mechanical (components of HVACR systems and piping systems) or electrical (power supply distribution) equipment, medical equipment, fire pump equipment, and uninterruptible power supplies for hospitals. Any analytical qualification of equipment should be peer-reviewed independently by qualified, Registered Design Professionals.

D-1.1.2 Certification Based on Testing.

Shake table tests conducted in accordance with either ICC-ES AC156, *Acceptance Criteria for Seismic Qualification by Shake-Table Testing of Nonstructural Components*, or a site-specific study, should first use uniaxial motions along each of the three principal axes of the equipment that is being tested. The measured response recorded with vibration response monitoring instrumentation should be reviewed to determine if out-of-plane response (in terms of peak amplitude) at a given location of instrumentation exceeds 20% of the in-plane response. The in-plane direction is the direction of horizontal test motions, while the out-of-plane direction is at a horizontal angle of 90 degrees with respect to the in-plane axis. An out-of-plane response (equipment relative acceleration or equipment deformation) that exceeds 20% of the in-plane response, for either horizontal test, indicates that significant cross-coupling is occurring. In that case, the final qualification test should be triaxial, with simultaneous phase-incoherent motions along all three principal axes. If out-of-plane response is less than 20% of the in-plane response for both horizontal tests, at each critical location instrumented, then the final qualification tests can be biaxial with motions in one horizontal and the vertical directions. After post-test inspection and functional compliance verification, the Unit Under Test (UUT) may be rotated 90 degrees about the vertical axis and biaxial testing for the other horizontal direction and vertical direction can be conducted. Normally, two biaxial tests, rather than a single triaxial test, would be conducted when a triaxial shake table is not available or the displacement capacity of a triaxial shake table in one direction is small.

The development of ICC-ES AC156 is documented in *ASCE Structures Congress Proceedings: Background on the Development of the NEHRP Seismic Provisions for Non-Structural Components and their Application to Performance Based Seismic Engineering* (Gillengerten, J.D., and Bachman, R.E., ASCE Structures Congress, 2003). For RC V facilities, the site-specific seismic site response analysis will result in a set of site-specific ground motions that define the seismic hazard. The building model could be analyzed with these motions to define predicted time-history motions at each location where critical equipment must be installed. From these building response motions, response spectra could be developed, using 5% of critical damping. If the equipment will be placed at several locations in the same building or in multiple buildings, a required response spectrum (RRS) could be developed that envelopes all the spectra generated from each building response record. As an alternative to the ICC-ES AC156 procedure, the equipment could be qualified with triaxial motions fit to the RRS, but generated according to ICC-ES AC156. A second alternative approach would be to test with the predicted time history motions that have the greatest response spectra amplitude at the measured natural frequency of the equipment in each of the principal directions. Using worst-case records would require that resonance search shake table

tests be conducted in each of the three principal directions as defined in ICC-ES AC156. All alternatives to ICC-ES AC156 equipment qualification testing require peer review of the development of test records and test plans by qualified, Registered Design Professionals. Post-test inspection and functional compliance verification would still be required in accordance with ICC-ES AC156.

D-1.1.3 Additional Certification Methods.

Three additional methods are permitted for defining equipment capacity: earthquake experience data, seismic qualification testing data, and the CERL Equipment Fragility and Protection Procedure. The use of these methods requires a peer review by a qualified, Registered Design Professional.

D-1.1.3.1 Earthquake Experience Data.

Earthquake experience data that were obtained by surveying and cataloging the effects of strong ground motion earthquakes on various classes of equipment mounted in conventional power plants and other industrial facilities may be used. Section 4.2.1 of the publication *Generic Implementation Procedure (GIP) for Seismic Verification of Nuclear Plant Equipment* (DOE 1992) provides these data. Based on this work, a Reference Spectrum would be developed to represent the seismic capacity of equipment in the earthquake experience equipment class. DOE/EH-0545, *Seismic Evaluation Procedure for Equipment in U.S. Department of Energy Facilities*, provides guidance on this procedure. A detailed description of the derivation and use of this Reference Spectrum is contained in DoE publication SAND92-0140, *Use of Seismic Experience Data to Show Ruggedness of Equipment in Nuclear Power Plants*. This document should be reviewed before using the Reference Spectrum. The Reference Spectrum and four spectra from which it is derived are shown in Figure 5.3-1 of DOE/EH-0545. The Reference Spectrum and its defining response levels and frequencies are shown in Figure 5.3-2 of the same document. When this approach is used, the Reference Spectrum is used to represent the seismic capacity of equipment, when the equipment is determined to have characteristics similar to the earthquake experience equipment class and meets the intent of the caveats for that class of equipment as defined in Chapter 8 of DOE/EH-0545.

D-1.1.3.2 Seismic Qualification Testing Database.

Data collected from seismic qualification testing of nuclear power plant equipment may be used in the certification of equipment. These data were used to develop generic ruggedness levels for various equipment classes in the form of Generic Equipment Ruggedness Spectra (GERS). The development of the GERS and the limitations on their use are documented in Electric Power Research Institute (EPRI) report NP-5223, *Generic Seismic Ruggedness of Power Plant Equipment in Nuclear Power Plants*. The non-relay GERS and limitations on their use are discussed in Chapter 8 of DOE/EH-0545, while the relay GERS are in Chapter 11 of the same document. The EPRI report should be reviewed by users of the GERS to understand the basis for them. The use of

either the Reference Spectrum or the GERS for defining equipment capacity requires careful review of the basis for them to ensure applicability to the equipment being evaluated.

D-1.1.3.3 CERL Equipment Fragility and Protection Procedure.

The CERL Equipment Fragility and Protection Procedure (CEFAPP), defined in USACERL Technical Report 97/58, may be used for defining equipment capacity. Similar to the other methods, CEFAPP defines a response spectrum envelope of the equipment capacity. This method requires a series of shake table tests to develop an actual failure envelope across a frequency range. This experimental approach requires greater effort than the ICC-ES AC156 qualification testing. However, the resulting failure envelope provides a more accurate and complete definition of capacity, rather than simply determining that the equipment survived a defined demand environment. Unlike the AC156 procedure, site-specific testing, or the other two additional methods, CEFAPP defines actual equipment capacity and provides information on modes of failure with respect to response spectra amplitudes and frequency of motion. Definitions of equipment capacity are more accurate with respect to frequency and mode of failure than can be established using the alternative methods. When equipment capacity is compared with the seismic demands at the various locations in which the equipment must be installed, the equipment vulnerability, if any, can be clearly defined in terms of predicted mode of failure and frequency. The procedure provides information on how to protect the equipment, using isolation, strengthening, or stiffening. The use of CEFAPP requires peer review of proposed test motions, the test plan, and use of the data, by qualified Registered Design Professionals.

D-1.1.3.4 Qualification of Power Substation Equipment.

IEEE Recommended Practice for Seismic Design of Substations (IEEE 693-2018) provides detailed guidance for the qualification of equipment used in power substations. This guidance should be used for the qualification of this equipment even if installed at facilities other than substations (e.g., power plants).

For SI: 1 inch = 25.4 mm, 1 square inch = 645.16 mm², 1 square foot = 0.0929 m², 1 pound per square foot = 0.0479 kN/m² = 0.0479 kPa, 1 pound = 0.004448 kN, 1 pound per cubic foot = 16 kg/m³.

- a. Where snow loads occur that are in excess of the design conditions, the structure must be designed to support the increased loads caused by drift buildup or greater snow loads determined by the *AHJ*. (See IBC Section 1608).
- b. See IBC Section 1604.8.3 for decks attached to exterior walls.
- c. Areas of occupiable roofs, other than roof gardens and assembly areas, be designed for appropriate loads as approved by the *AHJ*. Unoccupied landscaped areas of roof be designed in accordance with IBC Section 1607.13.3.
- d. Live load reduction is not permitted.
- e. Live load reduction is only permitted in accordance with Section 1607.13.1.2 or Item 1 of Section 1607.13.2.
- f. Live load reduction is only permitted in accordance with Section 1607.13.1.3 or Item 2 of Section 1607.13.2.
- g. Helipads supporting military aircraft must be designed to support the actual aircraft weight and impact loading due to landing.
- h. All attics with mechanical units must be designed for mechanical equipment room loading.
- i. For live loads on pedestrian bridges see AASHTO LRFD *Guide Specifications for the Design of Pedestrian Bridges*.

- j. ~~14\~~ *High density data center rack space should be verified for each project as these systems are rapidly evolving and have been known to exceed 400psf in some circumstances.* ~~14\~~

APPENDIX F COMPOSITES FOR BRIDGING APPLICATIONS [ADDITION]

F-1 INTRODUCTION.

F-1.1 Purpose and Scope.

This Appendix provides design resources to structural engineers interested in using polymer composite technologies for bridge applications. This Appendix is not intended to provide requirements for design and construction. Fiber reinforced polymer (FRP) composite materials and systems are now available that are not necessarily covered by the current AASHTO LRFD Bridge Design Specifications, but which may have performance and cost benefits in the repair and major rehabilitation and replacement of existing highway bridges within the DoD. This Appendix provides design considerations for polymer composites, references to guide specifications published by AASHTO, ACI, ASCE, FHWA, and case studies published by FHWA and USACE. The fiber reinforced polymer (FRP) technologies covered in this Appendix include glass FRP composite reinforcing bars, carbon FRP composite prestressing systems, FRP composite external strengthening and repair systems, and FRP composite elements including bridge piles and bridge decks. This appendix also includes information on thermoplastic materials for replacement of timber bridges including thermoplastic lumber, thermoplastic piles, and thermoplastic I-beams.

F-1.2 Applicability.

This Appendix applies only to polymer composite technologies for bridge applications. The guide specifications referenced herein are not intended to supplant proper training or the exercise of judgment by the Design Professional and state only the minimum requirements necessary to provide for public safety. The Design Professional may require the sophistication of the design or the quality of materials and construction to be higher than the minimum requirements. The Design Professional should be familiar with the provisions of the *AASHTO LRFD Bridge Design Specifications* and latest interim specifications. The decision to implement polymer composite technologies not currently covered by guide specifications should be made in consultation with the Service's lead Structural Engineering POC. This consultation is to ensure less developed technologies are implemented successfully.

F-1.3 Overview of Appendix.

Brief descriptions of the various sections of this appendix follow:

- F-2 – GENERAL. Provides a brief background on thermoset FRP composites and thermoplastic composites.
- F-3 – THERMOSET FRP COMPOSITE TECHNOLOGIES. Provides general design considerations for the use of thermoset FRP composites and reference to guide specifications and case studies for thermoset FRP composite technologies for bridge applications including non-prestressed

and prestressed concrete reinforcement, external strengthening systems for concrete, and FRP bridge elements including piles and decks.

- F-4 – THERMOPLASTIC TECHNOLOGIES. Provides general considerations for the use of thermoplastic technologies and reference to specification when available and case studies for thermoplastic technologies as replacement for timber bridge elements including dimensional lumber, piles, and beams.
- F-5 – REFERENCES. Lists the references included in this Appendix.
- F-6 – ABBREVIATIONS. Lists the abbreviations used in this Appendix.

F-2 GENERAL.

Composite materials are by definition a combination of two or more materials that differ in form and composition on the macro scale. The individual components maintain their phase and are not merged or melted into a new state. The result is an engineered material with desirable characteristics derived from the mechanical properties of the components. Composite materials have been used as construction materials for decades in the form of reinforced concrete and laminated timber products. Beginning in the 1960s, advances in material processing and the need for more durable materials led to the emergence of FRP composite materials.

The fiber reinforcement in an FRP composite provides the primary strength and stiffness while the polymer matrix transfers loads between fibers, ensures proper fiber alignment, and provides protection from environmental effects. Three types of fiber commonly used include glass, aramid, and carbon. Glass is the least expensive with lower strength and stiffness compared to carbon or aramid. Carbon is typically the most expensive with the highest strength and stiffness. As a general rule of thumb, carbon fiber can be around six to ten times as expensive as glass fiber. The fiber reinforcement can take the form of either continuous strands or woven/stitched fabrics.

The two broad families of polymers used are thermosets and thermoplastics. Thermosets are more commonly used in FRP composites due to their low curing temperature, workability, flowability, and resistance to creep, compared to thermoplastics. Thermosets cure by forming long hydrocarbon chains joined by crosslinking covalent bonds through a chemical reaction. Once formed, they cannot be melted or reformed by heat. Thermoplastics are composed of long hydrocarbon chains that are not chemically bonded through crosslinking and can move with respect to each other. Thermoplastic materials typically have high ductility and lower strength than thermoset composites and can be melted and reshaped by temperature. Due to these fundamental differences in chemical structure and mechanical behavior, this Appendix is divided into thermoset FRP composites (Section F-3) and thermoplastic materials (Section F-4).

F-3 THERMOSET FRP COMPOSITE TECHNOLOGIES.

F-3.1 Thermoset FRP Composite Design Considerations.

The following design considerations for thermoset FRP composites are not intended to be comprehensive but are to alert the reader that thermosetting FRP composite materials require different considerations than traditional construction materials. More information on design considerations can be found in the publications referenced throughout F-3.2.

F-3.1.1 Anisotropic behavior.

Thermoset FRP composite materials are anisotropic with strength properties highly dependent on fiber architecture. Composites have higher strengths in the primary direction of the fibers with lower strengths in the transverse direction. Composites with fibers oriented primarily in one direction are called unidirectional composites. Unidirectional composites are used primarily in tension as they have a lower compressive strength compared to tensile strength. As a result of this lower compressive strength, design philosophies for FRP reinforcement and external strengthening systems for concrete do not rely on the contribution of unidirectional composites in compression. FRP composites can also be designed with fiber architectures that orient fibers in multiple directions. This allows composites to be optimized for loading conditions. Multidirectional composite shapes will generally have higher strengths in tension than in compression.

F-3.1.2 Stiffness and ductility.

Glass FRP composites have a stiffness of around 5,000 ksi to 7,000 ksi and a much lower ductility than steel. This lower stiffness results in the majority of glass FRP composite designs being controlled by serviceability criteria rather than strength. Carbon FRP composites can have strength and stiffness that exceed certain grades of steel but have low ductility. Both glass and carbon FRP composites display a linear elastic behavior up until failure. This linear elastic behavior coupled with low ductility has led to conservative design criteria for FRP composite reinforcement for concrete, which reinforces the tensile zone to force failure to occur in concrete compression and limits the strain in the tensile bars (limited to around .008). As a result, FRP reinforced concrete will typically be controlled by a failure mode with low ductility. Retrofits and external strengthening systems for concrete are limited to applications where failure of a bonded repair would not result in the catastrophic failure of the structure. The publications cited in F-3.2 provide further discussions on the design guidance developed in light of these behaviors.

F-3.1.3 Creep and fatigue.

Thermoset FRP composites under sustained tensile load can suddenly rupture after a time period called the endurance time. This phenomenon is known as creep rupture or static fatigue rupture. Fatigue loading can also provide similar failure modes. Creep and fatigue rupture are designed for by limiting the sustained and fatigue stresses in FRP composite elements to a percentage of their ultimate strength. The sustained and fatigue stresses in most design criteria are conservatively limited to around 20% of ultimate strength for glass composites, 30% of ultimate strength for aramid composites,

and 50% of ultimate strength for carbon composites. Additional information on this topic is provided in the publications in F-3.2. Note that there are gaps in knowledge about the number of load cycles required to cause fatigue due to the effects of load reversals and about the creep response of FRP composite materials for certain applications. Research into these topics is still ongoing.

F-3.1.4 Durability.

Thermoset FRP composites are resistant to rot, insects, and corrosion. They have displayed good durability in highly corrosive environments leading to their applications in chemical storage tanks and as reinforcement in concrete. Ultra-violet (UV) radiation can degrade the polymer matrix, leading to reduced performance. UV degradation is designed for by adding UV-inhibitors to the resin during fabrication and by applying UV-resistant coatings to FRP composites exposed to direct sunlight. Durability considerations are designed for by applying material resistance factors based upon the type of FRP composite, its application, and its exposure conditions. For additional information on the general durability of FRP composites, refer to *ACI 440R Report on Fiber-Reinforced Polymer (FRP) Reinforcement for Concrete Structures*. The durability considerations found in *ACI 440R* apply directly to FRP composite reinforcement for concrete but the concepts discussed are generally applicable to other FRP composite technologies. Note that though thermoset FRP composites in many applications have demonstrated good durability, research into their long term performance is still on-going.

F-3.2 Thermoset FRP Composite Guidance and Case Studies.

The following section describes the most developed thermoset FRP composite technologies including recommended applications, current guide specifications, and case studies.

F-3.2.1 Glass Fiber Reinforced Polymer (GFRP) Reinforcing Bars.

The following applications may be suitable for deformed or sand-coated GFRP reinforcing bars, but the Design Professional should be aware of the design considerations for GFRP reinforcing bars as well as the limitations and applicability of current guidance before selecting GFRP reinforcing bars for any application:

- Reinforcement for normal weight concrete deck slabs, cast-in-place solid slab (longitudinally reinforced), and pre-cast deck bridges
- Reinforcement for normal-weight concrete beams, girders, and diaphragms.
- Reinforcement for normal-weight concrete piles, piers, and footings.
- Reinforcement for normal-weight concrete bridge railing.

F-3.2.1.1 Guidance.

The following guide specifications are available for GFRP concrete reinforcing bars:

- For guidance on the design of concrete bridge members reinforced with GFRP reinforcing bars, refer to *AASHTO LRFD Bridge Design Guide Specifications for GFRP Reinforced Concrete*. The guide specification should be reviewed carefully for its limitations and applicability as GFRP reinforcing bars may not be suitable for certain applications.
- For information on the characteristics and durability of non-prestressed FRP reinforcing bars in concrete, refer to *ACI 440.1R Guide for the Design and Construction of Structural Concrete Reinforced with Fiber-Reinforced (FRP) Bars*.
- For information on test methods to characterize FRP reinforcing bars, refer to *ACI 440.3R Guide Test Methods for Fiber-Reinforced Polymer (FRP) Composites for Reinforcing or Strengthening Concrete and Masonry Structures*.
- For information on construction specification for FRP reinforcing bars, refer to *ACI 440.5 Specification for Construction with Fiber-Reinforced Polymer Reinforcing Bars*.

F-3.2.1.2 Case Studies.

The following resources can be referred to for demonstrations and case studies related to the implementation of GFRP reinforcing bars for concrete bridge elements:

- For a case study on the use of GFRP reinforcing bars in a bridge replacement project completed by Maine DOT, refer to *Maine Demonstration Project: Hotel Road (Littlefields Bridge) Replacement Using Superstructure Slide-In Technology*. The report can be accessed via the following link: <https://www.fhwa.dot.gov/bridge/composite/cpdi.cfm>
- For a list of projects reports related to GFRP reinforcement, completed through the FHWA Innovative Bridge Research and Construction/Deployment (IBRC/IBRD) Program, refer to the FHWA website accessed through the following link: <https://www.fhwa.dot.gov/bridge/composite/str.cfm>.
- For a review of the state of the art for GFRP reinforcing bars, refer to *ACI 440R Report on Fiber-Reinforced Polymer (FRP) Reinforcement for Concrete Structures* and *ACI CODE-440.11-22: Building Code Requirements for Structural Concrete Reinforced with Glass Fiber-Reinforced Polymer (GFRP) Bars – Code and Commentary*.

F-3.2.2 Carbon Fiber Reinforced Polymer (CFRP) Prestressing Systems.

The following applications may be suitable for CFRP prestressing systems, but the Design Professional should be aware of the design considerations for CFRP prestressing systems as well as the limitations and applicability of current guidance before selecting CFRP prestressing systems for any application:

- Pretensioned reinforcement for normal weight concrete beams.
- Bonded and unbonded internally post-tensioned reinforcement for normal-weight concrete beams.

F-3.2.2.1 Guidance.

The following guide specifications are available for CFRP prestressing systems for concrete beams:

- For guidance on the design of concrete bridge beams prestressed with CFRP systems, refer to *AASHTO Guide Specification for the Design of Concrete Bridge Beams Prestressed with CFRP Systems*. The guide specification should be reviewed carefully for its limitations and applicability as CFRP prestressing systems may not be suitable for certain applications.
- For requirements not specifically addressed in the previously listed publication, refer to *ACI 440.4R Prestressing Concrete Structures with FRP Tendons* for additional information. For additional information on the design philosophy and research needs for CFRP pretensioned systems, also refer to *ACI 440.4R*.
- For additional recommendations for the design of CFRP prestressing systems, refer to the Florida Department of Transportation (FDOT) *Structures Manual Volume 4: Fiber Reinforced Polymer Guidelines (FRPG)*.

F-3.2.2.2 Case Studies.

The following resources can be referred to for demonstrations and case studies related to the implementation of CFRP prestressing systems for concrete bridge beams:

- For a case study on the use of CFRP reinforcement in concrete bridge beams conducted by Virginia Transportation Research Council, refer to *Concrete Beams Prestressed Using Carbon Fiber Reinforced Polymers, Final Report VTCR 19-R29*. The report can be accessed through the following link: <https://www.fhwa.dot.gov/bridge/composite/resources.cfm>
- For a list of project reports related to CFRP prestressing systems completed through the FHWA Innovative Bridge Research and Construction/Deployment (IBRC/IBRD) Program, refer to the FHWA website accessed through the following link: <https://www.fhwa.dot.gov/bridge/composite/str.cfm>.
- For a review of the state of the art for CFRP prestressing systems, refer to *ACI 440R Report on Fiber-Reinforced Polymer (FRP) Reinforcement for Concrete Structures* and *ACI 440.4R Prestressing Concrete Structures with FRP Tendons*.

F-3.2.3 FRP External Strengthening Systems.

The following applications may be suitable for FRP repair and strengthening systems but the Design Professional should be aware of the design considerations for FRP repair and strengthening systems as well as the limitations and applicability of current guidance before selecting FRP repair and strengthening systems for any application:

- External reinforcement of concrete flexural members on the tension face to improve flexural strength.
- Wrapping of existing concrete beams and columns to improve shear strength.
- Confinement of reinforced concrete columns to enhance strength and ductility.
- Strengthening of earthquake damaged and seismically deficient structures.

F-3.2.3.1 Guidance.

The following guide specifications are available for FRP external strengthening and repair systems for concrete bridge elements:

- For guidance on the design of FRP systems for repair and strengthening of concrete bridge members, refer to *AASHTO Guide Specifications for Design of Bonded FRP Systems for Repair and Strengthening of Concrete Bridge Elements*. The guide specification should be reviewed carefully for its limitations and applicability as FRP strengthening systems may not be suitable for certain applications.
- For requirements not specifically addressed in the listed publication and for design examples, refer to *ACI 440.2R Guide for the Design and Construction of Externally Bonded FRP Systems for Strengthening Concrete Structures*.
- Note that *FDOT Structures Manual Volume 4: FRPG* recommends that carbon be the primary reinforcement for FRP composite systems used in repair or strengthening of concrete. It also recommends that if either a pre-cured laminate or wet layup system is used, the resin and adhesive should be a thermoset epoxy formulation specifically designed to be compatible with the fibers or pre-cured shapes. In wet layup systems, the manual recommends limiting shear and flexural reinforcement to no more than three layers except as required for anchorages.

F-3.2.3.2 Case Studies.

The following resources can be referred to for demonstrations and case studies related to the implementation of FRP external strengthening systems for concrete bridge elements:

- For a state of the art of FRP strengthening systems compiled by FHWA, refer to *Report on Techniques for Bridge Strengthening, FHWA-HIF-18-041*. This report can be accessed through the following link:
<https://www.fhwa.dot.gov/bridge/composite/cpdi.cfm>
- For a list of project reports related to strengthening and damage repair of bridges with FRP strengthening systems completed through the FHWA Innovative Bridge Research and Construction/Deployment (IBRC/IBRD) Program, refer to the FHWA website accessed through the following link:
<https://www.fhwa.dot.gov/bridge/composite/str.cfm>.

F-3.2.4 FRP Structural Bridge Elements.

The following applications may be suitable for FRP bridge elements but the Design Professional should be aware of the design considerations for FRP bridge elements as well as the limitations and applicability of current guidance before selecting FRP bridge elements for any application:

- FRP composite bridge fender systems.
- FRP composite stay-in place formwork for concrete bridge decks.
- Concrete-filled FRP composite tubes for bridge culverts and bearing piles.
- FRP composite bridge decking as replacement for concrete bridge decks.

F-3.2.4.1 Guidance.

The following guide specifications and pre-standards are available for FRP composite bridge elements:

- For guidance on the design of concrete-filled FRP tubes as structural members in bridges, refer to *AASHTO LRFD Guide Specifications for Design of Concrete-Filled FRP Tubes for Flexural and Axial Members*. The guide specifications apply to concrete-FRP composite members only. The limitations of this guide specification should be reviewed before use.
- For information on the design of FRP composite members for pedestrian bridges, refer to *AASHTO Guide Specification for Design of FRP Pedestrian Bridges*. Note that this guide specification is from 2008, refers to the outdated *AASHTO 17th edition*, and is only applicable to pedestrian bridges.
- For information on the design of pultruded structural members, refer to *ASCE Pre-standard for Load & Resistance Factor Design (LRFD) of Pultruded FRP Structures*. Note that this document provides design equations for pultruded structural shapes but is not specifically for bridge applications.

- For information on the design of connections for pultruded structural shapes, refer to *ASCE Manuals and Reports on Engineering Practice No. 102, Design Guide for FRP Composite Connections*. Note that this guide contains general design considerations and equations for bolted, adhesive, and mixed connections, but it is not specifically for bridge applications.

F-3.2.4.2 Case Studies.

The following resources can be referred to for demonstrations and case studies related to the implementation of FRP structural bridge elements:

- For a case study on the design and implementation of a composite bridge decking system conducted by FHWA, refer to *Composite Bridge Decking, Publication No. FHWA-HIF-13-029*. The report can be accessed through the following link: <https://www.fhwa.dot.gov/bridge/composite/cpdi.cfm>
- For information on a demonstration of an FRP composite bridge deck to replace a reinforced concrete bridge deck completed by USACE-ERDC, refer to *ERDC/CERL TR-16-16 Demonstration and Validation of a Lightweight Composite Bridge Deck Technology as an Alternative to Reinforced Concrete*.
- For information on a demonstration of a hybrid composite beam (HCB) system in a bridge replacement project at Fort Knox, Kentucky completed by USACE-ERDC, refer to *ERDC/CERL TR-16-22 Demonstration of Corrosion-Resistant Hybrid Composite Bridge Beams for Structural Applications*. The HCB system consisted of a glass fiber reinforced plastic (GFRP) shell, tension reinforcement using stainless steel cables, low-density foam core, and a concrete arch that provided compression reinforcement.
- For a case study on the implementation of composite piles conducted by FHWA, refer to *A Laboratory and Field Study of Composite Piles for Bridge Substructures, FHWA-HRT-04-043*. The report can be accessed through the following link: <https://www.fhwa.dot.gov/bridge/composite/cpdi.cfm>
- For a list of project reports related FRP pultruded structural members and composite bridge decking completed through the FHWA Innovative Bridge Research and Construction/Deployment (IBRC/IBRD) Program, refer to the FHWA website accessed through the following link: <https://www.fhwa.dot.gov/bridge/composite/str.cfm>.

F-4 THERMOPLASTIC TECHNOLOGIES.

Thermoplastics materials have recently emerged as a durable and cost-effective alternative to timber for short span bridges. Thermoplastic materials require no chemical preservatives, are low-maintenance and corrosion-resistant, and have reduced life cycle costs. While this technology is still under development and guidance is limited, this technology has been included to allow readers full exposure to all polymer composites.

F-4.1 Thermoplastic Material Considerations.

The following considerations for thermoplastic materials are not intended to be comprehensive but are to alert the reader that these materials require different considerations than traditional construction materials and thermoset FRP composite materials. More considerations can be found in the publications referenced throughout F-4.2.

F-4.1.1 Procurement.

Guidance on the design and use of thermoplastic materials for structural applications is limited. To implement thermoplastic materials, a performance-based procurement methodology is recommended. The following is one possible approach to this method:

To begin, the Owner would specify the performance requirements of the structure to be procured including the anticipated loads, site conditions, geometric requirements, and serviceability limits. The contractors completing the design-build process would be required to provide the ASTM testing reports of any products used in their design for review by the Owner or his consultant. Possible ASTM specifications to be used for this testing are referenced in section F-4.2.3.1. The design would then be developed based upon values from this testing, which would be reduced to provide factors of safety agreed upon by the Design Professional. Any elements or components identified as critical by the Design Professional or Owner would then be fabricated and tested to the satisfaction of all parties. As elements are fabricated, proof testing would be conducted at predefined check points to ensure that a representative batch of the material has the required mechanical properties. After the construction of the structure, the structure would be field-tested with the operating loads to check that the serviceability requirements are met.

F-4.1.2 Non-Homogenous and Anisotropic Behavior.

Thermoplastic materials are produced through an extrusion process. The thermoplastic materials are melted, pushed through a die or into a mold to form structural shapes, and cooled until hardened. The process cools the outer surface of the material faster than the interior. This results in the outer layers forming a dense, thick skin while the interior can develop voids and air bubbles. The thick outer skins provide the majority of the structural capacity to the member. Thermoplastic profiles should never be notched or split longitudinally to limit warping and to retain the capacity of the components. The extrusion process also produces a distinctive “grain” along the length of the component, parallel to the direction of extrusion. The differences in tensile and compressive strength parallel and perpendicular to this grain can be significant and should be taken into account. This directionality consideration is similar to that in timber design.

F-4.1.3 Viscoelasticity.

Since the hydrocarbon chains making up thermoplastic materials are not chemically cross-linked and can slide past each other, thermoplastic materials display viscoelastic

behavior. This viscoelasticity results in a non-linear response to applied loading that is dependent upon the rate of loading, the duration of the loading, and the ambient temperature. This viscoelastic response is unique to thermoplastic materials and research into this behavior is still needed.

- Thermoplastic materials will display changes in ductility and stiffness, dependent upon the rate at which a load is applied. For example, if the same load is applied to a thermoplastic flexural member at two different load rates, the higher load rate will result in a stiffer, less ductile response in the member, compared to the same load applied to the member at the lower load rate.
- Thermoplastic materials will undergo creep if exposed to sustained loads. This tendency for creep is designed for by 1) reducing the modulus of elasticity in calculations involving long-term loads, to provide conservative design values, 2) limiting flexural members to short span lengths, and 3) incorporating chopped fiber or FRP reinforcement within the thermoplastic member to improve creep resistance.
- Thermoplastic materials are affected by ambient temperature. If exposed to extreme heat, thermoplastic materials will display an increase in ductility and a reduction in stiffness. If exposed to extreme cold, thermoplastic materials will display reduced ductility and an increase in stiffness which can lead to brittle failures. These responses to ambient temperature can be avoided by limiting the application of thermoplastics to regions with moderate temperatures.

F-4.1.4 Thermal Expansion.

Thermoplastic materials have high coefficients of thermal expansion compared to traditional construction materials, expanding and contracting noticeably in the direction of the “grain” as temperatures fluctuate. As a result, connections should be designed to accommodate this thermal movement, especially if joining materials with different coefficients of thermal expansion. Note that additional research is needed to more fully quantify this behavior and guidance for thermoplastic connection design and testing is limited.

F-4.1.5 Design Methodology.

Thermoplastic materials are designed using timber design methodologies with adjustment factors for thermoplastics. Allowable Stress Design (ASD) methods are used instead of LRFD as thermoplastic materials have not been calibrated due to their viscoelastic properties and limited empirical data. Thermoplastic materials are less stiff than timber and the majority of thermoplastic material designs are controlled by serviceability criteria and not strength.

F-4.2 Thermoplastic Material Guidance and Case Studies.

The following section describes the emerging thermoplastic technologies suitable for replacements of timber, including recommended applications, current guidance when available, and case studies.

F-4.2.1 Structural Grade Thermoplastic Lumber.

The following applications may be suitable for structural grade thermoplastic lumber, but the Design Professional should be aware of the design considerations for thermoplastic lumber as well as the limitation and applicability of current specifications:

- Decking as a replacement for timber decking.
- Pedestrian railing as a replacement for timber railing.

F-4.2.1.1 Guidance.

There is no AASHTO guidance for structural grade thermoplastic lumber. The following specifications can be reviewed for design and procurement information:

- For procedures to establish design strengths, flame spread index, and knock-down factors relative to load duration, creep rupture, temperature, and stress over time for polyethylene-based structural grade plastic lumber (SPGL), refer to *ASTM D7568 Standard Specification for Polyethylene-Based Structural-Grade Plastic Lumber for Outdoor Applications*. The limitations and applicability of this specification should be reviewed before use.
- For procedures to establish suitable span lengths, flame spread index, slip resistance, and knock-down factors relative to load duration, temperature, and creep adjustment for polyolefin-based decking boards, refer to *ASTM D6662 Standard Specification for Polyolefin-Based Plastic Lumber Decking Boards*. The limitations and applicability of this specification should be reviewed before use.
- For guidance on the procurement and construction of thermoplastic dimensional lumber, refer to *UFGS 06 10 00 Rough Carpentry*. The limitations and applicability of this specification should be reviewed before use.

F-4.2.1.2 Case Study.

For Information on construction recommendations, mechanical connection detailing, and inspection techniques for thermoplastic lumber, refer to *ERDC/CERL TR-17-45 Demonstration of Thermoplastic Composite I-Beam Design Bridge at Camp Mackall, NC*.

F-4.2.2 Thermoplastic Piles.

The following applications may be suitable for thermoplastic pile, but the Design Professional should be aware of the design considerations for thermoplastic piles as well as the limitation and applicability of current specifications:

- Piles as a direct replacement for timber piles.
- Fenders as a direct replacement for timber fenders.

F-4.2.2.1 Guidance.

There is no AASHTO guidance for thermoplastic piles. The following specifications can be reviewed for design and procurement information:

- For design criteria for round and rectangular cross-section polymer piles in axial and lateral load-bearing applications, refer to *ASTM D7258 Standard Specification Polymeric Piles*. The limitations and applicability of this specification should be reviewed carefully before use.
- For guidance on the procurement of thermoplastic piles, refer to *UFGS 35.59.13.14 20 Polymeric Piles*. The limitations and applicability of this specification should be reviewed carefully before use.

F-4.2.2.2 Case Study.

For information on the construction and inspection of thermoplastic piles for a thermoplastic bridge, refer to *ERDC/CERL TR-17-45 Demonstration of Thermoplastic Composite I-Beam Design Bridge at Camp Mackall, NC*.

F-4.2.3 Thermoplastic Structural I-beams.

The following applications may be suitable for thermoplastic structural I-beams, but the Design Professional should be aware of the design considerations for thermoplastic I-beams as well as the lack of guidance and limitations of this technology:

- Thermoplastic I-beams to replace timber beams in vehicular bridges
- Thermoplastic I-beams to replace timber beams in railroad bridges

F-4.2.3.1 Discussion.

In 2009, advances in thermoplastic material processing resulted in the development of prefabricated thermoplastic I-beams for bridge applications. The efficient shape of the I-beam reduced member weight and fabrication cost while maintaining strength and flexural rigidity. The beams were flow-molded from comingled recycled polyolefins (primarily high-density polyethylene (HDPE)) with a combination of thermoplastic coated

fiber material or/and polystyrene, poly methyl methacrylate (PMMA), or a combination of the three).

This thermoplastic I-beam technology was used to replace three timber vehicular bridges and two timber railroad bridges on U.S. Army installations as part of initial demonstration of thermoplastic bridges. After these demonstrations, five full scale beams similar to the beams in the bridges were evaluated through full-scale flexural testing. The results of these tests are documented in *ERDC/CERL TR-17-18 Full Scale Testing of Thermoplastic Composite I-Beams for Bridges*. It is strongly recommended that this report be reviewed before considering the use of these beams. During the testing, two of the beams displayed brittle failures (less than 0.2% outer fiber strain as recorded during testing). The brittle failures occurred after the two beams had been cyclically loaded and the failure loads were lower than the ultimate loads applied to the beam during this cyclic loading. This behavior indicates that the flexural strength of the beams was reduced due in some part to the cyclical loading. While the beams displayed significant deflections before failure, more research and testing is needed to fully identify the possible failure modes of these thermoplastic I-beams.

No guidance is currently available for the design of thermoplastic I-beams, but it is possible to procure them with a performance-based procurement process using lessons learned from previous case studies and testing the beams using the following ASTM specifications:

- For flexural strength testing, refer to *ASTM D6109 Standard Test Methods for Flexural Properties of Unreinforced and Reinforced Plastic Lumber and Related Products*. This standard is for “as manufactured” components. As such, it is not a material property test method.
- For compression strength testing, refer to *ASTM D6108 Standard Test Method for Compressive Properties of Plastic Lumber and Shapes*. This standard is for “as manufactured” components. As such, it is not a material property test method.
- For mechanical connection strength testing, including screws, nails, and staples, refer to *ASTM D6117, Standard Test Methods for Mechanical Fasteners in Plastic Lumber and Shapes*. This standard does not cover the testing of bolted connections.
- For testing to evaluate thermal movement, refer to *ASTM D6341 Standard Test Method for Determination of the Linear Coefficient of Thermal Expansion of Plastic Lumber and Plastic Lumber Shapes Between -30 and 140°F (-34.4 and 60°C)*.

F-4.2.3.2 Case Studies.

The following resources can be referenced for information on the implementation and testing of thermoplastic I-beams:

Three vehicular thermoplastic bridges using thermoplastic I-beams replaced deteriorated timber bridges at Camp Mackall, NC. The bridges were designed for HS25 loading and can support an M1 Abrams Tank. These demonstrations are documented in the following reports:

- Refer to *ERDC/CERL TR-17-45 Demonstration of Thermoplastic Composite I-Beam Design Bridge at Camp Mackall, NC* for details on the development, design, construction, and inspection for these bridges.
- Refer to *ERDC/GSL TR-10-19 Field Testing and Load Rating of the World's First Thermoplastic Bridge* for results from load rating conducted on one of these bridges.
- Refer to *ERDC/CERL TR-11-43 Remote Monitoring of a Thermoplastic Composite Bridge at Camp Mackall, NC* for information on a remote monitoring system installed on one of these bridges. This system recorded the deflection of the bridge each time a vehicle passed over the bridge.
- Refer to *ERDC/CERL TR-17-18 Full Scale Testing of Thermoplastic Composite I-Beams for Bridges* for results of material characterization and flexural tests conducted on five of these thermoplastic I-beams.

Two thermoplastic railroad bridges were built at Ft. Eustace, Virginia with thermoplastic I-beams. The railroad bridges were designed to carry the Cooper E60 load and the 260 kip alternate live load on four axles.

- Refer to *World's First Thermoplastic Railroad Bridges* for information on the development, design, construction, and load testing of these thermoplastic railroad bridges.

Summary

Composite materials in bridge design have the advantages of light weight, high strength and strong corrosion resistance, which contribute to low maintenance and long service life for structures. This contributes to life cycle cost savings and provides a long-term economic advantage over traditional materials such as steel and concrete. Because of these special properties, composite materials can have a better application in bridge engineering.

Bridge strengthening techniques using FRP composites can be used to restore capacity or add capacity for a bridge to remain open to legal and unrestricted loads. Composite materials can provide solutions to address emergency situations in a timely manner.

Some of the disadvantages involve higher short-term and uncertain long-term costs, uncertain durability and lack of ductility.

Steel, concrete, and timber bridge design involves utilization of appropriate material according to design standards, codes, and best practices predicated on the use of well-

documented and standardized material types. Although there have been considerable advances made in developing design codes and procedures for composite strengthening, there is little standardization of material specifications and construction guidelines. This is due to the fact that many composite materials are producer specific. Because of this, designing with bridge composite materials may sometimes require more specialized knowledge in material behavior and manufacturing process compared to other materials.

Despite the difficulties mentioned above, ACI Committee 440 has been able to develop and publish ACI CODE-440.11-22: *Building Code Requirements for Structural Concrete Reinforced with Glass Fiber-Reinforced Polymer (GFRP) Bars—Code and Commentary*. The 2024 IBC adopted a proposed change submitted by ACI as follows.

1901.2.1 Structural Concrete with GFRP reinforcement.

Cast-in-place structural concrete internally reinforced with glass fiber reinforced polymer (GFRP) reinforcement conforming to ASTM D7957 and designed in accordance with ACI CODE 440.11 shall be permitted where fire resistance ratings are not required and only for structures assigned to seismic design category A.

ACI CODE-440.11-22 is also expected to be adopted by ACI CODE-318-25.

APPENDIX G GLASS FIBER-REINFORCED POLYMER (GFRP) BARS FOR CON- CRETE STRUCTURES [ADDITION]

G-1 INTRODUCTION.

G-1.1 Purpose and Scope.

This Appendix provides design resources to structural engineers interested in using glass fiber-reinforced polymer (GFRP) reinforcement in concrete structures. It is written for structural engineers proficient in the design of concrete structures using ACI 318, *Building Code Requirements for Structural Concrete*. New standards developed by ASTM and ACI for GFRP bars are discussed along with other supporting guides and reports. Other types of FRP bars, such as carbon, basalt, or aramid are not addressed, since comprehensive standards for these fibers are not yet developed. This Appendix identifies the limits on the use of GFRP reinforcement in concrete structures and key design considerations. For a more general overview on FRP material, reference Appendix F, Composites for Bridging Applications.

G-1.2 Applicability.

This Appendix applies to concrete structures that are designed in accordance with ACI CODE 440.11-22, *Structural Concrete Reinforced with Glass Fiber-Reinforced Polymer (GFRP) Bars--Code and Commentary*. ACI CODE 440.11-22 contains the requirements for design, durability, and construction using GFRP reinforcement. ACI CODE 440.11-22 is written similarly to ACI 318, *Building Code Requirements for Structural Concrete*, and references ACI 318 for requirements that apply independently of the type of reinforcement used.

Historically, the most common application of GFRP bars is to reinforce highway bridge decks in areas where deicing salts are used on the roads and cause severe corrosion to conventional steel reinforcement. Other applications include marine structures such as seawalls or piers, flood mitigation channels, parking garages, water tanks, structures supporting MRI machines, and rail plinths for electric trains. Design reasons to use GFRP bars for other types of structures are:

- They do not corrode in the presence of chloride ions
- They do not interfere with electromagnetic fields
- They are thermally nonconductive

G-1.3 Limitations to Use.

The greatest limitation to the use of GFRP bars is related to fire. The fire ratings are very low to zero and not standardized at this time. Suggested ratings are given in the commentary to ACI CODE 440.11-22. For this reason, DoD does not allow the use of GFRP reinforcement in:

- Structures that have a fire rating above zero. Also, similar structures that may not have a fire rating but could collapse due to fire and threaten life safety (for example, GFRP reinforcing not allowed for upper deck of double-deck piers, and comparable structures similarly affected by heat zones).
- Architectural cast-in-place concrete
- In architectural precast concrete, unless all connections use steel

Other limitations on GFRP use discussed later in this Appendix are:

- Do not use in seismic force-resisting systems for Seismic Design Categories B, C, D, E, and F.
- GFRP reinforcement is permitted in structural members not part of the seismic force-resisting system for Seismic Design Categories A, B, and C.
- GFRP reinforcement is not recommended for lightweight concrete due to insufficient research data.
- GFRP use in prestressed concrete systems is not currently covered.

G-1.4 Overview of Appendix.

Brief descriptions of the various sections of this appendix follow:

- G-2 – GENERAL. Provides an explanation on the use of ASTM D7957/D7957D with ACI CODE 440.11-22.
- G-3 – GFRP REINFORCING BARS. The GFRP reinforcing bar as defined in ASTM D7957/D7957M is described. A comparison with steel reinforcement is provided.
- G-4 – DESIGN. Provides an overview of the design philosophy. Identifies design limitations that are different from those for steel reinforced structures.
- G-5 – DURABILITY. Provides an overview of the environmental and design aspects to be considered when using GFRP.
- G-6 – CONSTRUCTION. Provides a brief discussion on the use of GFRP bars in construction. Construction specification requirements are given in UFGS 03 30 00, Cast-in-Place Concrete.
- G-7 – REFERENCES. Lists the references included in this Appendix.
- G-8 – ABBREVIATIONS. Lists the abbreviations used in this Appendix.

G-2 GENERAL.

Concrete structures with GFRP bars are designed using two standards, ACI CODE 440.11-22, *Structural Concrete Reinforced with Glass Fiber-Reinforced Polymer (GFRP) Bars--Code and Commentary*, and ASTM D7957/D7957M, *Standard Specification for Solid Round Glass Fiber Reinforced Polymer Bars*. ASTM D7957/D7957M contains the material properties need for design. ACI CODE 440.11-22 contains the requirements for design. Additional design guidance can be found in ACI 440.1 and Nanni et. al (2014). The process of design has been generally agreed on since the early 2000s. In the United States, guidance was provided in ACI 440.1, *Guide for the Design and Construction of Structural Concrete Reinforced with FRP Bars*, in 2001. Other international standard organizations developed similar design methodologies: CSA S806, *Design and construction of building structures with fiber-reinforced polymers*, in 2002; and *fib Bulletin 40, FRP Reinforcement in RC Structures*, in 2007. ACI 440.1 was the basis for the ACI CODE 440.11-22 code. ACI CODE 440.11-22 is dependent on ACI 318 for common structural concrete design requirements and is compatible with ASCE 7 for easy integration into practice in the United States.

One of the difficulties in bringing FRP bars to common use is the wide variety of fibers and resins along with varying manufacturing processes that can greatly change the properties of the material. Designers had to contact the manufacturer to find the properties of the material they planned to use. However, the test methods used to measure the properties were not standard. The last several years have been spent standardizing test methods and finding agreement from manufacturers on minimum performance levels, material properties, and sizes. Glass fiber is the most used fiber and is the first fiber to have a full standard for use in concrete reinforcement. ASTM D7957/D7957M has minimum guaranteed values for GFRP properties such as ultimate tensile force, transverse shear strength, modulus of elasticity, and bond strength. Manufacturers can exceed these minimum values and designers are permitted to use the higher actual values. The designer, however, would need to know the manufacturer before design and the manufacturer would need to submit certified material tests for confirmation.

G-3 GFRP REINFORCING BARS.

GFRP bars are made of continuous strands of glass fiber encapsulated in a protective resin. The bars have strength comparable to steel reinforcement in tension, but lower strength in the transverse direction. This behavior is called anisotropic, whereas steel is isotropic. The material behavior of GFRP is explained in more detail in Appendix F. The surface of the bar is modified to create a mechanical interlock with the concrete for bond. The modifications may be a sand coating or fibers wound around the bar, creating deformations.

G-3.1 Material Specification.

The material specification for GFRP reinforcing bars is ASTM D7957/D7957M. The specification establishes property limits and test methods for qualification and certification. Minimum guaranteed values for design are established. These limits must be met but the manufacturer may exceed these limits. The specification does not have grades like steel. It provides a baseline strength and durability that a designer may use without having to have a greater understanding of the fiber material and encapsulating resin.

G-3.2 Tensile Strength.

The specification establishes bar sizes similar to steel reinforcement. The bar sizes range from No. 2 to No. 10. Although there are many shapes for GFRP bars, round bars are used because of designers' and contractors' familiarity with steel reinforcement. The stress in the GFRP bar at its breaking strength decreases as bar size increases. The rate of stress reduction can vary; thus, the specification requires a minimum guaranteed ultimate tensile force rather than a stress. Consequently, the designer will have to calculate the ultimate tensile stress for each bar size. For instance, the tensile strength of a No. 2 bar is 124 ksi (855 MPa) compared to a No. 10 bar, for which it is 77 ksi (531 MPa).

GFRP bar bends are formed during the manufacturing process rather than bending a straight bar after production, which would rupture the bar. The specification establishes a minimum ultimate tensile force of a bent portion of the bar. Due to the anisotropic behavior of GFRP bars, the tensile strength at bends is lower than that of the straight portion of the bar. The specification sets this lower strength at 60 percent of ultimate tensile force of a bar. ACI CODE 440.11-22 limits the shear reinforcement stress to be compatible with this limit.

G-3.3 Material Properties.

GFRP reinforcing bars are similar in strength to steel reinforcing bars in tension. Table G-1 provides a comparison of GFRP and steel material properties. Some key observations:

- The GFRP bars are different from steel bars in that they do not yield. They demonstrate elastic behavior until they fracture.
- GFRP is about one-fourth the stiffness of steel, thus controlling deflection at service loads is essential to mitigate excessive cracking.
- Shear strength of the GFRP bar depends mostly on the resin. The bar is not as strong as steel when used as a dowel.
- GFRP bars are about one-fourth of the weight of steel. This makes the material easier to handle in the field, which can reduce construction time.

Table G-1 Comparison of GFRP and steel material properties

Property	ASTM D7957/D7957M GFRP	ASTM A615/A615M Steel
Minimum yield strength	None, elastic until failure	40, 60, 80, 100 ksi
Ultimate tensile strength	77 ksi to 124 ksi	60, 90, 105, 115 ksi
Modulus of Elasticity	6500 ksi	29,000 ksi
Transverse shear strength	19 ksi	Same as yield strength
Density	Approx. 135 lb/ft ³ at 70% fiber mass content	493 lb/ft ³

G-4 DESIGN.

The design methodology used in ACI CODE 440.11-22 is strength design, similar to the methodology in ACI 318. The main difference is that GFRP reinforcement is linear elastic until failure, unlike steel reinforcement. Steel reinforced members are designed to yield before failure. This provides some warning that an overloading of the structure is occurring before collapse. GFRP reinforced members do not have a yield plateau, so extra capacity is needed to prevent sudden failures due to overloading. This is done by reducing the Φ factors. A full explanation of the rationale is given in the Commentary to Chapter 21 of ACI CODE 440.11-22. The result is that, in flexure, either GFRP rupture or concrete crushing is an acceptable failure mode. The design requirements and discussion are provided in Chapter 22 of ACI CODE 440.11-22.

G-4.1 Shear Design.

Shear design philosophy in ACI CODE 440.11-22 is similar to that of ACI 318. The main difference is that GFRP reinforcement has lower axial stiffness than steel. This shifts the neutral axis in design, creating a smaller compression region in the cross section. The result is larger cracks. The equation for V_c has been modified to account for the lower stiffness in the longitudinal reinforcement. The GFRP shear reinforcement calculations are similar to those per ACI 318. A stress limit is placed on the shear reinforcement due to the reduced tensile strength of the reinforcement at the bend of a bar. The design requirements and discussion are provided in Chapter 22 of ACI CODE 440.11-22.

G-4.2 Serviceability.

Serviceability requirements in ACI CODE 440.11-22 often control the design of concrete slabs, joists, or beams with GFRP reinforcement. Service level effects to be considered are deflection, distribution of flexural reinforcement to reduce cracking, shrinkage and temperature reinforcement, and permissible tensile stresses. Deflections must be calculated in ACI CODE 440.11-22; one cannot choose a minimum depth for a span as permitted in ACI 318. The ACI CODE 440.11-22 calculations have been modified to use the Bischoff equations as was done in ACI 318-19. Requirements for the distribution of flexural reinforcement and shrinkage and temperature reinforcement were slightly modified to account for the less stiff material. Most importantly, a limit on service stress

has been added to address creep rupture and fatigue, two important limit states that need to be addressed in GFRP reinforcement. A maximum sustained stress limit of 0.3 times the ultimate tensile stress is given. A method to calculate the sustained stress is based on the unfactored moment due to the sustained load on the member. This equation can also be used to address fatigue loading. The design requirements and discussion are provided in Chapter 24 of ACI CODE 440.11-22.

G-4.3 Development and Lap Splices.

Development of GFRP reinforcement is accomplished with a straight bar end or hook. GFRP reinforcement cannot yield so the design philosophy takes a shift. The development length of the bar need only be such that the stress of the controlling limit state rather than the ultimate strength of the bar is developed. Also, only 90-degree hooks are effective in developing the bars, due to a lack of ductility. Use lap splices for reinforcement continuity. The code provides the design requirements for a mechanical device, however, there are no commercially available devices that currently can meet these requirements for GFRP reinforcement. The commercially available mechanical splices developed for steel reinforcement damage GFRP bars and reduce strength; therefore, they are prohibited from being used with GFRP bars. The tie, stirrup, hook, and spiral provisions are modified to reflect the practice of manufacturing GFRP shapes. The design requirements and discussion are provided in Chapter 25 of ACI CODE 440.11-22.

G-4.4 Other Design Considerations.

In I-1.2, Applicability, DoD does not allow the use of GFRP reinforcement in structures that have a fire rating. Other key observations about designing with GFRP reinforcement according to ACI CODE 440.11-22:

- Do not count on moment redistribution. Since GFRP does not yield, plastic hinges cannot develop, nor can it yield in areas of greater restraint to allow for moment redistribution.
- Strength of GFRP reinforcement in compression is ignored.
- GFRP reinforcement is not recommended for lightweight concrete due to insufficient research data.
- Use of GFRP reinforcement in prestressed concrete systems is currently not covered.
- Use of GFRP reinforcement in diaphragms are not covered.
- Do not use GFRP reinforcement in seismic force-resisting systems for Seismic Design Categories B, C, D, E, and F.

- GFRP reinforcement is permitted in structural members not part of the seismic-force-resisting system for Seismic Design Categories A, B, and C.

G-5 DURABILITY

Because it is a relatively new construction material, there is some concern regarding the long-term durability of GFRP reinforcement. FRP reinforcement has been in service in North America since 1993. Since that time, there have been a couple hundred bridge decks and other structures that have been built with FRP bars.

G-5.1 Strength and Stiffness.

Depending on the materials and manufacturing process used, GFRP bars can be susceptible to reduced strength and stiffness when exposed to moisture or high-alkaline environments. Much of the testing to gage this sensitivity, however, has been done with short-term experiments using environments that are much more aggressive than the field conditions. Extrapolation of these results to field conditions and expected lifetimes is not possible in the absence of real-time data. To account for these detrimental effects, the GFRP reinforcement needs to be manufactured to a minimum quality that mitigates these effects. ASTM 7957/7957M establishes the quality assurance for long-term performance; in general, the bars have proven to be durable.

Although GFRP reinforcement has shown to be durable to date, only predictive models based on accelerated tests can estimate how long the reinforcement will remain at design level strengths. To account for the uncertainty of predictive models, ACI CODE 440.11-22 has placed an environmental reduction factor, C_E , of 0.85 to the guaranteed ultimate tensile strength. Over time, the actual performance of GFRP reinforcement will be compared to the predictive models and whether an environmental factor is necessary will be evaluated. The design requirements and discussion are provided in Chapter 20 of ACI CODE 440.11-22.

G-5.2 Creep and fatigue.

Time-dependent effects that can degrade the strength of GFRP over time are creep rupture and static fatigue. The design aspects of these effects are discussed in Section G-4.2, as part of the serviceability requirements. Creep rupture is the sudden failure of FRP material due to sustained loads over time. Static fatigue is similar in that a sudden failure will occur under sustained cyclical loading. Both can be mitigated if the stress in the reinforcement due to the sustained load or cyclical loading is restricted to a lower limit.

G-5.3 Exposure to Temperatures and Sunlight.

The potential for exposure to high temperatures needs to be considered when using GFRP reinforcement. The resin in the reinforcement will soften as the temperature approaches the glass transition temperature. ASTM D7957/D7957M requires the mean glass transition temperature to be at least 212 deg F (100 deg C). ACI CODE 440.11-22

suggests that GFRP bars should not be used in environments with a service temperature higher than 27 deg F (15 deg C) below the glass transition temperature. This calculates to an in-service limit of 185 deg F (85 deg C).

Ultra-violet radiation can be detrimental to GFRP reinforcement if exposed for long period of times to the sun before being placed in concrete. ACI 440.5 recommends if GFRP bars are stored outside for more than 4 months, they should be covered with opaque plastic. The requirement in UFGS 03 30 00, Cast-in-Place Concrete, places this limit at 2 months.

G-6 CONSTRUCTION

Construction specifications for GFRP reinforcement has been added to UFGS 03 30 00, Cast-in-Place Concrete. The information was developed from the requirements of ACI 440.5. The development of ASTM D7957/D7957M simplified the specification of GFRP reinforcement. Prior to its development, specifiers had to identify all the test methods and limits necessary for quality assurance. Manufacturers were providing different reinforcement shapes and sizes of reinforcement. ASTM D7957/D7957M established a standard bar size chart similar to steel reinforcement.

Key observations on construction with GFRP reinforcement.

- If the surface of the bar is damaged, it will need to be replaced. Visible damage is defined in the specification.
- On-site storage: cover the bars from the sun if exposed more than 2 months; and prevent exposing bars to greater than 120 °F.
- Concrete cover is different than it is for steel reinforcement.
- Support reinforcement with dielectric material or steel coated with dielectric material.
- Field cutting is permitted but bars cannot be field bent.
